1

Introduction

In the two years since Java's first release, the language has matured to become a complete platform. Java now provides a complete operating system, distributed computing with RMI and the CORBA bridge, a component architecture (JavaBeans), a middleware layer (Enterprise JavaBeans), the server toolkit, and the WebTop environment. Having proven successful, many Java-based applications have matured with the language, and now need a Java-based mail and messaging framework. The Java Mail API described in this specification satisfies that need.

The Java Mail API provides a set of abstract classes defining objects that comprise a mail system. The API defines classes like Message, Store and Transport. The API can be extended and can be subclassed to provide new protocols and to support new product functions when necessary.

In addition, the API provides concrete subclasses of the abstract classes. These subclasses, including MimeMessage and MimeBodyPart, implement widely used Internet mail protocols and conform to specifications RFC822, RFC2045. They are ready to be used in application development.

1.1 Target Audience

The JavaMail API is designed to serve several audiences:

- Client, server, or middleware developers interested in building Java-based mail and messaging applications, whether client, server or middleware.
- Application developers who need to "mail-enable" their applications.
- Service Providers who need to implement specific access and transfer protocols. For example; a telecommunications company can use the Java Mail API to implement a PAGER Transport protocol, that sends mail messages to alphanumeric pagers.

1.2 Acknowledgments

The authors of this specification are John Mani, Bill Shannon, Max Spivak, Kapon Carter and Chris Cotton. We would like to acknowledge the following people for their comments and feedback on the initial drafts of this document:

- Terry Cline, John Russo, Bill Yeager and Monica Gaines: Sun Microsystems.

- Arn Perkins and John Ragan: Novell, Inc.
- Nick Shelness: Lotus Development Corporation.
- Juerg von Kaenel: IBM Corporation.
- Prasad Yendluri, Jamie Zawinski, Terry Weissman and Gena Cunanan: Netscape Communications Corporation.

Goals and Design Principles

The JavaMail API is designed to add mail-enable functions to simple applications easily, and also to support the creation of sophisticated user interfaces. It includes appropriate convenience classes which encapsulate common mail functions and protocols. It fits with other Java packages in order to facilitate its use with other Java APIs, and it uses familiar Java programming models.

The JavaMail API is therefore designed to satisfy the following development and runtime requirements:

- Simple, straightforward class design is easy for a developer to learn and implement.
- Use of familiar concepts and programming models support code development that interfaces well with other Java APIs.
 - Uses familiar exception-handling and JDK 1.1 event-handling programming models.
 - Uses features from the Java Activation Framework (JAF) to handle access to data based on data-type, and to facilitate the addition of data types and commands on those data types. The JavaMail API provides convenience functions to simplify these coding tasks.
- Lightweight classes and interfaces make it easy to add basic mail-handling tasks to any application.
- Supports the development of robust mail-enabled applications, which can handle a variety of complex mail message formats, data types, and access and transport protocols.

The JavaMail API draws heavily from IMAP, MAPI, CMC, c-client and other messaging system APIs - many of the concepts present in these other systems are also present in the JavaMail API. It is simpler to use because it uses Java language features not available to these other APIs, and because it uses the Java object model to shelter applications from implementation complexity.

The JavaMail API design is driven by the needs of the applications it supports - but it is also important to consider the needs of API implementors. It is critically important to enable the implementation of Java-based messaging systems that interoperate with existing messaging systems-- especially Internet mail. It is also important to anticipate the development of new messaging systems. The JavaMail API conforms to current standards while not being so constrained by current standards that it stifles future innovation.

The JavaMail API supports many different messaging system implementations - different message stores, different message formats, and different message transports. The JavaMail API provides a set of base

classes and interfaces that define the API for client applications. Many simple applications will only need to interact with the messaging system through these base classes and interfaces.

JavaMail subclasses can expose additional messaging system features. For instance, the `MimeMessage` subclass exposes and implements common characteristics of an Internet mail message, as defined by RFC822 and MIME standards. Developers can subclass JavaMail base classes to provide the implementations of particular messaging systems, such as IMAP4, POP3, and SMTP.

The base JavaMail classes include many convenience APIs that simplify use of the API, but don't add any functionality. The implementation subclasses are not required to implement those convenience methods. The implementation subclasses must implement only the core classes and methods that provide functionality required for the implementation.

Alternately, a messaging system can choose to implement all of the JavaMail API directly, allowing it to take advantage of performance optimizations possible, perhaps through use of batched protocol requests. The IMAP4 protocol implementation takes advantage of this approach.

The JavaMail API uses the Java language to good effect to strike a balance between simplicity and sophistication. Simple tasks are easy, and sophisticated functionality is possible.

3

Architectural Overview

This Section describes the JavaMail architecture, defines major classes and interfaces comprising that architecture, and lists major functions that the architecture implements.

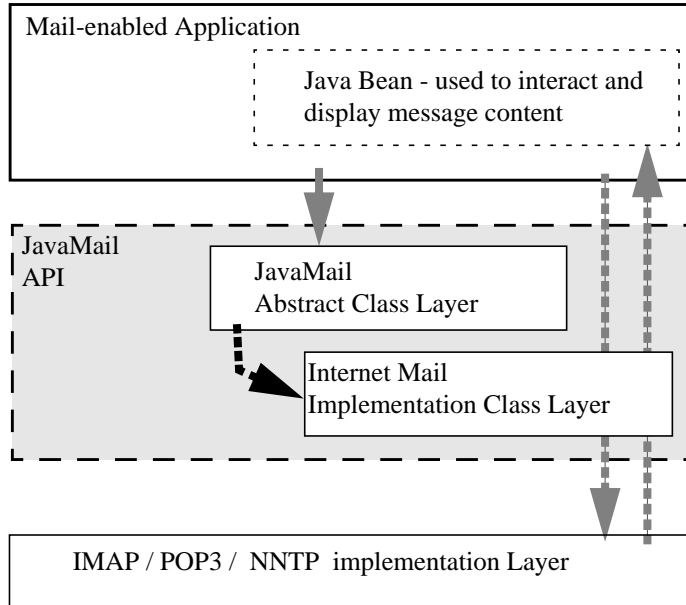

JavaMail provides elements that are used to construct an interface to a messaging system, including system components and interfaces. While this Specification does not define any specific implementation, JavaMail does include several classes that implement RFC822 and MIME Internet messaging standards and protocols. These classes are delivered as part of the JavaMail class package.

3.1 JavaMail Layered Architecture

The JavaMail architectural components are layered as shown below:

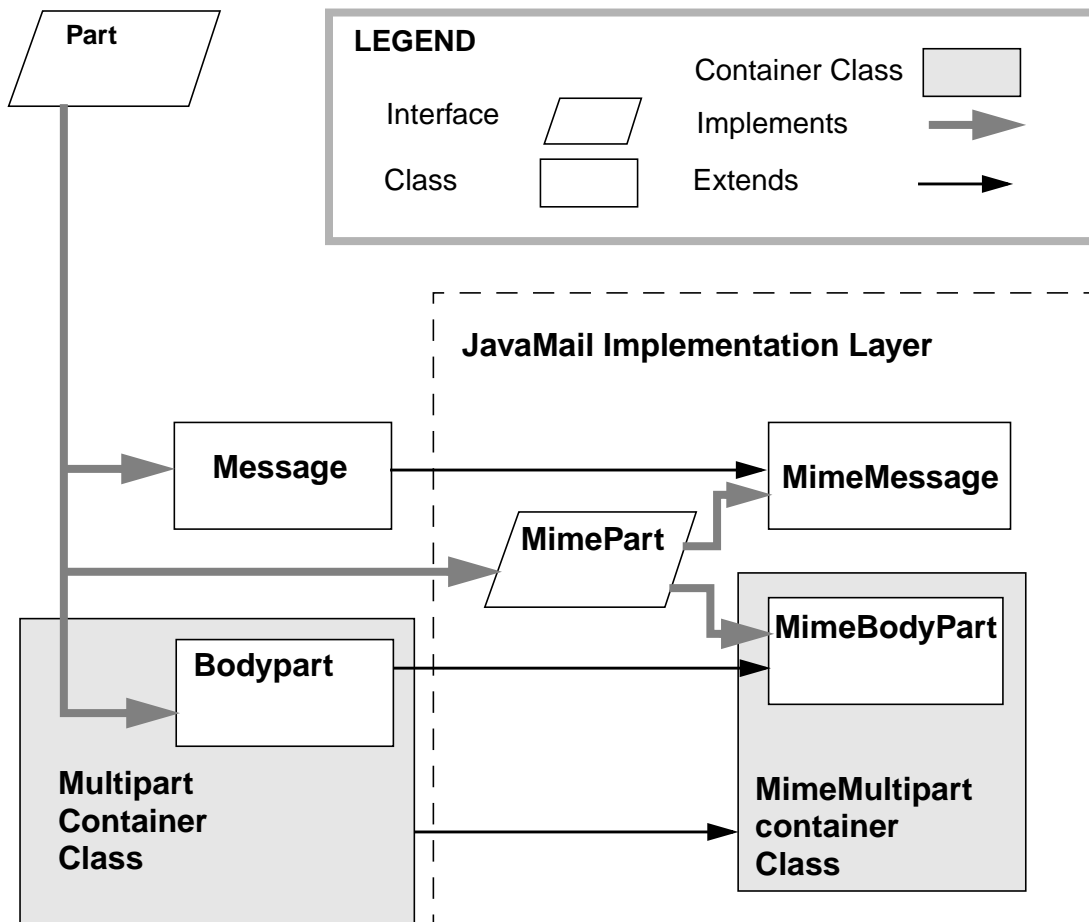

- The Abstract Layer declares Classes, Interfaces and abstract methods intended to support mail handling functions that all mail systems support. API elements comprising the Abstract Layer are intended to be subclassed and extended as necessary, in order to support standard data types, and to interface with message access and message transport protocols as necessary.
- The internet implementation layer implements part of the abstract layer using internet standard protocols - RFC822 and MIME.
- JavaMail uses the Java Activation Framework (JAF) in order to encapsulate message data, and to handle commands intended to interact with that data. Interaction with message data should take place via JAF-aware JavaBeans, which are not provided by the JavaMail API.

JavaMail clients use the JavaMail API and Service Providers implement the JavaMail API. The layered design architecture allows clients to use the same JavaMail API calls to send, receive and store a variety of messages using different data-types, from different message stores, and using different message transport protocols.

3.2 JavaMail Class Hierarchy

The figure below shows major classes and interfaces comprising the JavaMail API. See “Major JavaMail API Components” for brief descriptions of all components shown on this diagram.

3.3 The JavaMail Framework

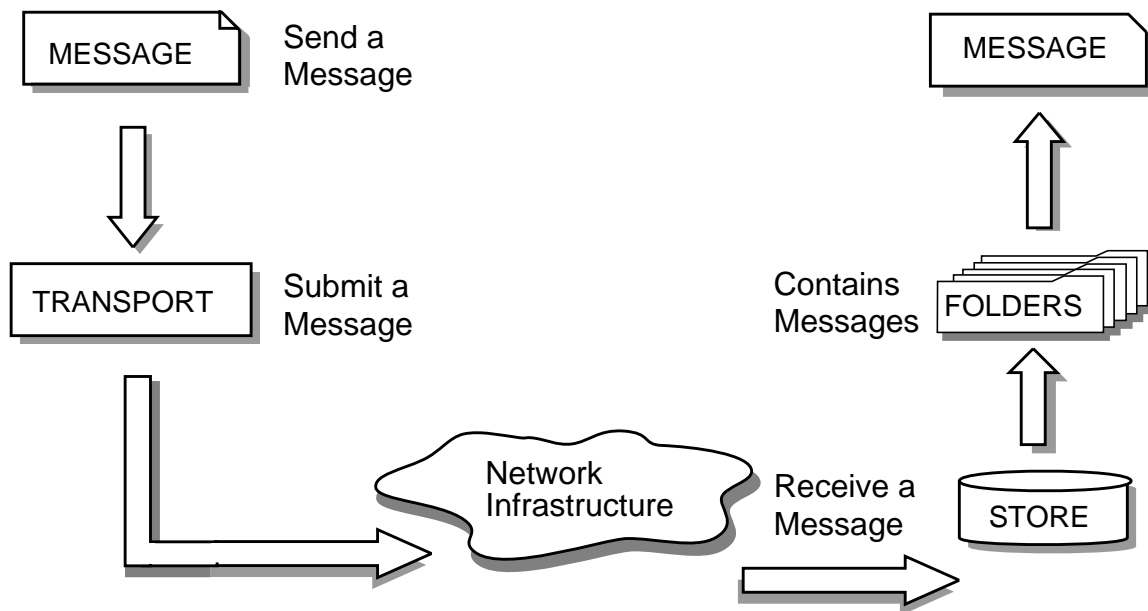

The JavaMail API is intended to perform the following functions, which comprise the standard Mail handling process for a typical client application:

- Create a Mail Message consisting of a collection of header attributes and a block of data of some known data type, as specified in the `Content-Type` header field. JavaMail uses the `Part` interface and the `Message` class to define a mail message. It uses the JAF-defined `DataHandler` object to contain data placed into the message.
- Create a session object, which authenticates the user, and controls access to the message store and transport.

- Send the message to its recipient list.
- Receive a message from a message store.
- Execute a high-level command on a retrieved message. High-level commands like *view* and *print* are intended to be implemented via JAF-Aware JavaBeans.

Note – The JavaMail framework does not define mechanisms that support message delivery, security, disconnected operation, directory services or filter functionality. Security, disconnected operation and filtering support will be added in future releases.

This figure illustrates the JavaMail message-handling process.

3.4 Major JavaMail API Components

This Section reviews major components comprising the JavaMail architecture.

3.4.1 The Message Class

Message is an abstract class that defines a set of attributes and a content for a mail message. Message attributes specify addressing information and define the structure of the content, including the content type. The content is represented as a `DataHandler` object that wraps around the actual data.

The `Message` class implements the `Part` interface. `Part` defines attributes that are required to define and format data content carried by a `Message` object, and to interface successfully to a mail system. The `Message` class adds `From`, `To`, `Subject`, `Reply-To`, and other attributes necessary for message routing via a message transport system. When contained in a `Folder`, a `Message` object also has a set of flags associated with it. `JavaMail` also provides `Message` subclasses that support specific messaging implementations.

The content of a `Message` is a collection of bytes, or a reference to a collection of bytes, encapsulated within a `Message` object. `JavaMail` has no knowledge of the data type or format of the message content. A `Message` object interacts with its content through an intermediate layer - **the Java Activation Framework (JAF)**. This separation allows a `Message` object to handle any arbitrary content and to transmit it using any appropriate transmission protocol, by using calls to the same API methods. The `Message` recipient usually knows the content data type and format, and knows how to handle that content.

The `JavaMail` API also supports multipart `Message` objects, where each `Bodypart` defines its own set of attributes and content.

3.4.2 Message Storage and Retrieval

Messages are stored in `Folder` objects. A `Folder` can contain subfolders in addition to messages, thus providing a tree-like folder hierarchy. The `Folder` class declares methods that fetch, append, copy and delete Messages. `Folder` can also fire events to components registered as event listeners.

The `Store` class defines a database that holds a folder hierarchy together with its messages. The `Store` also specifies the *access* protocol that accesses folders and retrieves messages stored in folders. `Store` also provides methods to establish a connection to the database, to fetch `Folders` and to destroy a connection. Service providers implementing Message Access protocols (IMAP4, POP3 etc.) start off by subclassing `Store`. A user typically starts a session with the Mail system by connecting to a particular `Store` implementation.

3.4.3 Message Composition and Transport

A client creates a new message by instantiating an appropriate `Message` subclass. It sets attributes like the recipient addresses and the subject, and inserts the content into the `Message` object. Finally, it sends the `Message` by invoking the `Transport.send()` method.

The `Transport` class models the transport agent that routes a message to its destination addresses. This class provides methods that send a `Message` to a list of recipients. Invoking the `Transport.send()` method with a `Message` object identifies the appropriate transport based on its destination addresses.

3.4.4 The Session Class

The `Session` class defines global and per-user Mail-related properties that define the interface between a mail-enabled client and the network. `JavaMail` system components use the `Session` object to set and get specific properties. The `Session` class also provides a default authenticated session object that desktop applications can share. `Session` is a final concrete class. It cannot be subclassed.

The Session also acts as a factory for Store and Transport objects that implement specific access and transport protocols. By calling the appropriate factory method on a Session object, the client can obtain Store and Transport objects that support specific protocols.

3.5 The JavaMail Event Model

The JavaMail event model conforms to the Java JDK 1.1 Event model specification, as described in the JavaBeans Specification. The JavaMail API follows the design patterns defined in the Beans Specification for naming events, event methods and event listener registration.

All events are subclassed from MailEvent. Clients listen for specific events by registering themselves as listeners for those events. Events notify listeners of state changes as a session progresses. During a session, a JavaMail component fires a specific event-type to notify objects registered as listeners for that event-type. The JavaMail Store, Folder, and Transport classes are event sources. This Specification describes a specific event in the Section that describes the class that fires that event.

3.6 Using the JavaMail API

This Section defines the syntax and lists the order in which a client application calls some JavaMail methods in order to access and open a Message located in a folder:

A JavaMail client typically begins a mail handling task by obtaining the default JavaMail Session object.

```
Session session = Session.getDefaultInstance(  
    props, authenticator);
```

The client uses the Session object's `getStore()` method to connect to the default Store. The `getStore()` method returns a Store object subclass that supports the access protocol defined in the user properties object, which will typically contain per-user preferences.

```
Store store = Session.getStore();  
store.connect();
```

If the connection is successful, the client can list available folders in the Store, and then fetch and view specific Message objects.

```
// get the INBOX folder  
Folder inbox = store.getFolder("INBOX");  
  
// open the INBOX folder  
inbox.open(Folder.READ_WRITE);  
  
Message m = inbox.getMessage(1);           // get Message # 1  
String subject = m.getSubject();           // get Subject  
Object content = m.getContent();           // get content  
..  
..
```

Finally, the client closes all open Folders, and then closes the Store.

```
inbox.close(); // Close the INBOX
store.close(); // Close the Store
```

See “Examples Using the Mail API” for a more complete example.

4

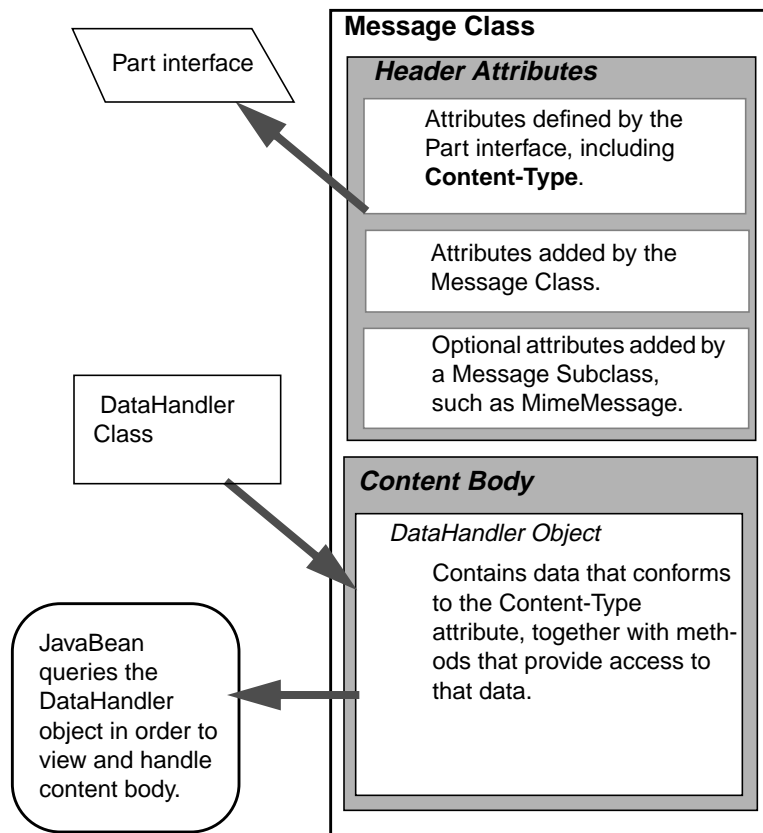

The Message Class

Message is an abstract class that defines a set of attributes and a content for a mail message. Message attributes specify message addressing information and define the structure of the content, including the content type. The content is represented by a `DataHandler` object that wraps around the actual data. The Message class is an abstract class that implements the `Part` interface.

Message subclasses can implement several standard message formats. For example, the JavaMail API provides the `MimeMessage` class, that extends `Message` in order to implement the RFC822 and the MIME standards. Implementations typically can construct themselves from byte streams and generate byte streams for transmission.

A Message subclass instantiates an object that holds message content, together with attributes that specify addresses for the sender and recipients, structural information about the message, and the content type of the message body. Messages placed into a `Folder` also have a set of flags that describe the state of the message within the folder.

The figure below illustrates the Message class structure.

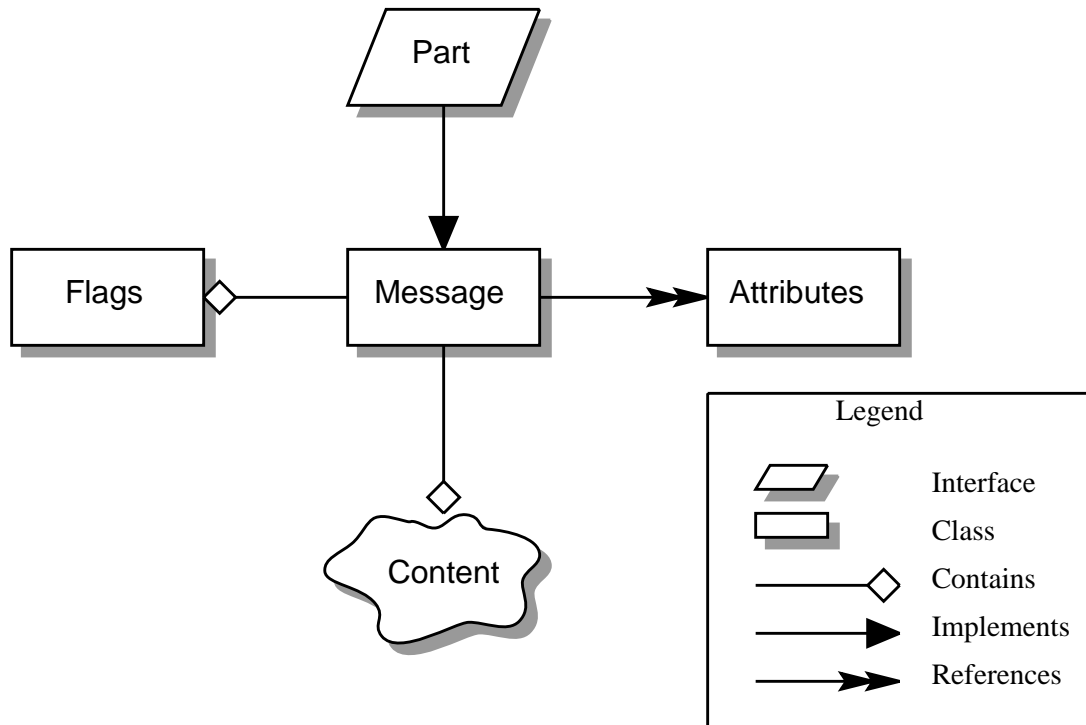

The Message object has no direct knowledge of the nature or semantics of its content. This separation of structure from content allows the message object to contain any arbitrary content.

Message objects are either retrieved from a Folder or constructed by instantiating a new Message object of the appropriate subclass. Messages stored within a Folder are sequentially numbered, starting at 1. An assigned message number can change when the folder is expunged, since the expunge operation removes deleted messages from the folder and also rennumbers the remaining messages.

A Message object can contain multiple parts, where each part contains its own set of attributes and content. The content of a Multipart Message is a Multipart object that contains BodyPart objects representing each individual part. The Part interface defines the structural and semantic similarity between the Message class and the BodyPart class.

The figure below illustrates a Message instance hierarchy, where the Message contains attributes, a set of flags, and content. See “MimeMessage Object Hierarchy” for an illustration of the MimeMessage object hierarchy.

The Message class provides methods to perform the following tasks:

- Get, Set and Create its attributes and content:

```
public String getSubject() throws MessagingException;
public void setSubject(String subject)
    throws MessagingException;
public String[] getHeader(String name)
    throws MessagingException;
public void setHeader(String name, String value)
    throws MessagingException;
public Object getContent()
    throws MessagingException;
public void setContent(Object content, String type)
    throws MessagingException
```

- Save changes to its containing folder.

```
public void saveChanges()  
    throws MessagingException;
```

This method also ensures that the Message header fields are updated to be consistent with the changed message contents.

- Generate a bytestream for the Message object.

```
public void writeTo(OutputStream os)  
    throws Exception, MessagingException;
```

This byte stream can be used to save the message or send it to a Transport object.

4.1 The Part Interface

The Part interface defines a set of standard headers common to most mail systems, specifies the data-type assigned to data comprising a content block, and defines set and get methods for each of these members. It is the basic data component in the JavaMail API and provides a common interface for both the Message and the BodyPart classes. See the JavaMail API documentation for details.

Note – A Message object can not be contained directly in a multipart object, but must be embedded in a BodyPart first.

4.1.1 Message Attributes

The Message class adds its own set of standard attributes to those it inherits from the Part interface. These attributes include the sender and recipient addresses, the subject, flags, and sent and received dates. The Message class also supports non-standard attributes in the form of Headers. See the JavaMail API Documentation for the list of standard attributes defined in the Message class. Not all messaging systems will support arbitrary headers, and the availability and meaning of particular header names is specific to the messaging system implementation.

4.1.2 The ContentType Attribute

The ContentType attribute specifies the data type of the content, following the MIME typing specification (RFC 2045). A MIME type is composed of a primary type that declares the general type of the content, and a subtype that specifies a specific format for the content. A MIME type also includes an optional set of type-specific parameters.

JavaMail API components can access content via these mechanisms:

As an input stream	The Part interface declares the <code>getInputStream()</code> method, that returns an input stream to the content. Note that Part implementations must decode any mail-specific transfer encoding before providing the input stream.
As a DataHandler object	The Part interface declares the <code>getDataHandler()</code> method, that returns a <code>javax.activation.DataHandler</code> object that wraps around the content. The DataHandler object allows clients to discover the operations available to perform on the content, and to instantiate the appropriate component to perform those operations. See “The JavaBeans Activation Framework” for details describing the DataTyping framework
As a Java object	The Part interface declares the <code>getContent()</code> method, that returns the content as a Java object. The type of the returned object is dependent on the content data type. If the content is of type multipart, the <code>getContent()</code> returns a Multipart object, or a Multipart subclass object. <code>getContent()</code> returns an input stream for unknown content-types. Note that <code>getContent()</code> uses the DataHandler internally to obtain the native form.

The `setDataHandler(DataHandler)` method specifies content for a new Part object, as a step towards the construction of a new Message. Part also provides some convenience methods to set up most common content types.

Part provides the `writeTo()` method that writes its byte stream in mail-safe form suitable for transmission. This byte stream is typically an aggregation of the Part attributes and the byte stream for its content.

4.2 The Address Class

The Address class represents email addresses. Address is an abstract class. Subclasses provide implementation-specific semantics.

4.3 The BodyPart Class

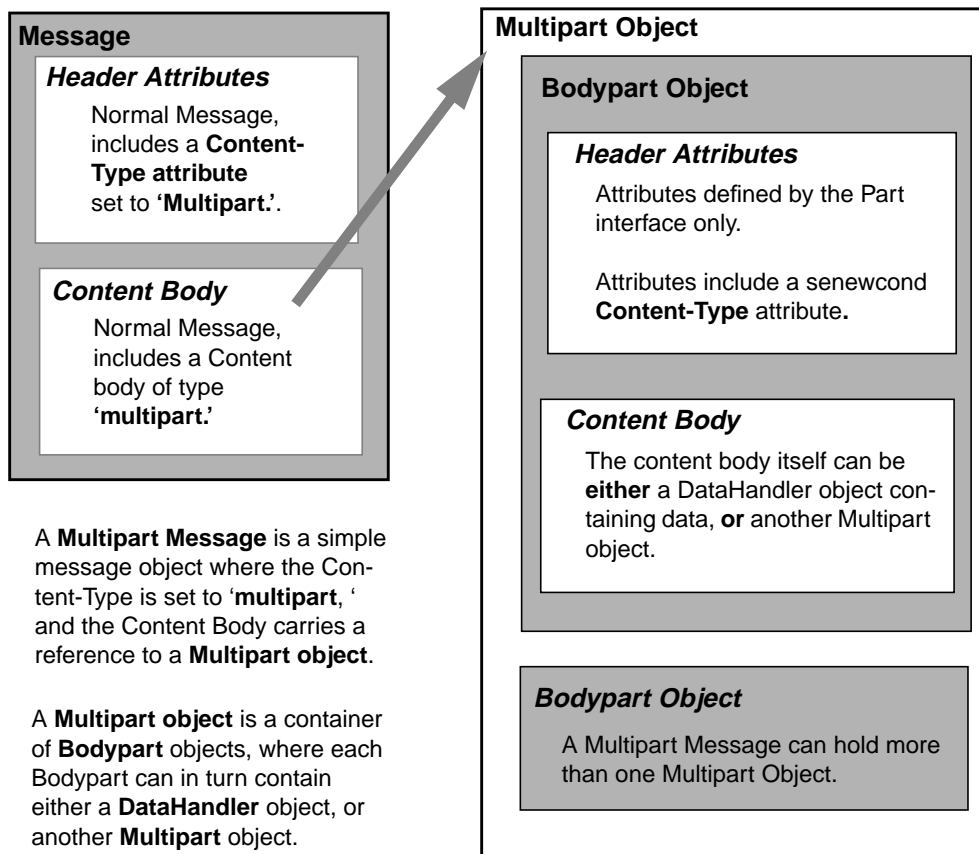

BodyPart is an abstract class that implements the Part interface, in order to define the attribute and content body definitions that Part declares. It does not declare attributes that set From, To, Subject, ReplyTo, or other address header fields, as a Message object does.

A BodyPart object is intended to be inserted into a Multipart container, later accessed via a Multipart Message.

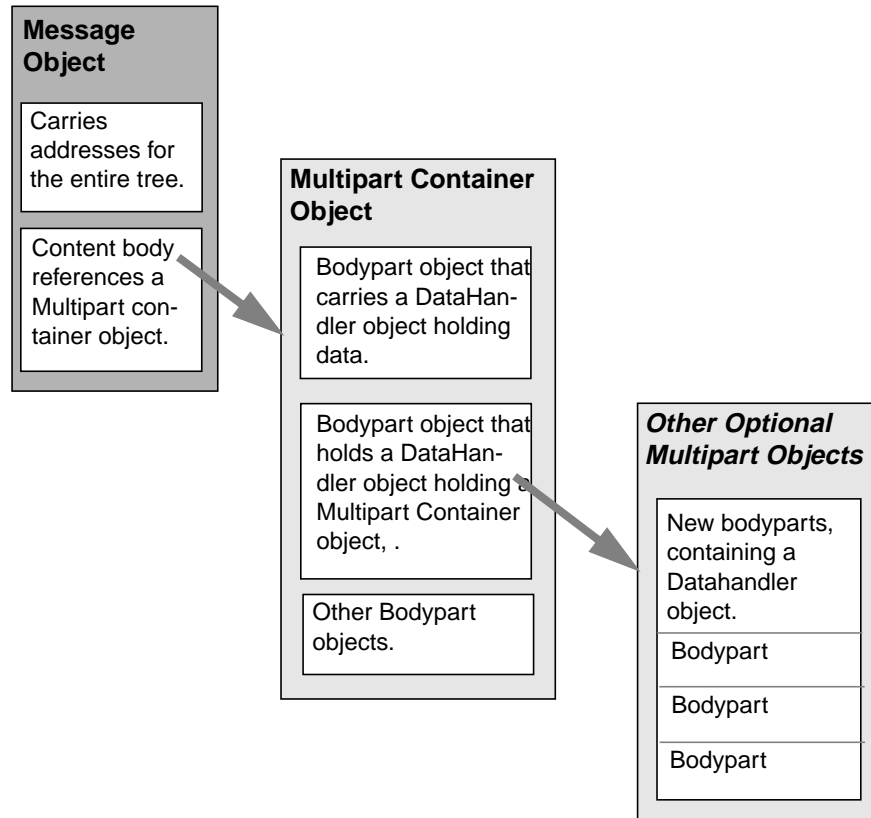

4.4 The Multipart Class

The Multipart class implements Multipart Messages. A Multipart Message is a Message object where the content-type specifier has been set to *multipart*. Multipart is a container class that contains objects of type Bodypart. A Bodypart object is an instantiation of the Part interface-- it contains either a new Multipart container object, or a DataHandler object.

The figure below illustrates the structure and content of a Multipart Message:

Note that Multipart objects can be nested to any reasonable depth within a Multipart Message, in order to build an appropriate structure for data carried in DataHandler objects. Therefore, it is important to check the ContentType header for each BodyPart element stored within a Multipart container. The figure below illustrates a typical nested Multipart Message.

Typically, the client calls `getContentType()` to return the `ContentType` of a message. If `getContentType()` returns a MIME-type whose primary type is *multipart*, then the client calls `getContent()` to return the Multipart container object.

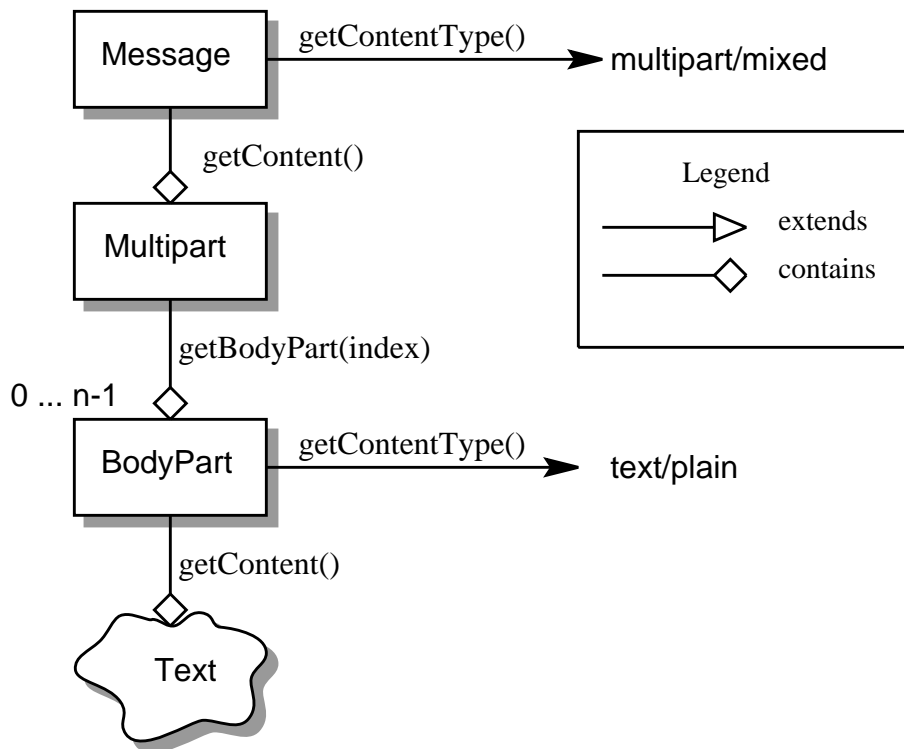

Multipart supports several methods that get, create, and remove individual `BodyPart` objects.

```

public int getCount() throws MessagingException;
public Body getBodyPart(int index)
    throws MessagingException;
public void addBodyPart(BodyPart part)
    throws MessagingException;
public void removeBodyPart(BodyPart body)
    throws MessagingException;
public void removeBodyPart(int index)
    throws MessagingException;
  
```

Multipart implements the `javax.beans.DataSource` interface. It can act as the `DataSource` object for `javax.beans.DataHandlers` and `javax.beans.DataContentHandlers`. This allows message-aware content handlers to handle Multipart data sources more efficiently, since the data has already been parsed into individual parts.

This diagram illustrates the structure of a Multipart Message, and shows associated Message and Multipart calls for a typical call sequence returning a bodypart containing text/plain content.

In this figure, the `ContentType` attribute of a Message object indicates that it holds a multipart content. Use the `getContent()` method to obtain the Multipart object.

This code sample below shows the retrieval of a Multipart object. See “Examples Using the Mail API” for examples that traverse a Multipart Message and create new Multipart Messages.

```

Multipart mp = (Multipart)message.getContent();
int count = mp.getCount();
BodyPart body_part;

```

```

for (int i = 0; i <= count; i++)
    body_part = mp.getBodyPart(i);

```

4.5 The Flags Class

Flags objects carry flag settings that describe the state of a Message within its containing folder. Message.getFlags() returns a Flags object that holds all the flags currently set for that message.

The setFlags(Flags f, boolean set) method sets the specified set of flags for that Message. The add(Flags.Flag f) method on a Flags object sets the specified flag; the contains(Flags.Flag f) method returns whether the specified flag is set.

ANSWERED	Clients set this flag to indicate that this Message has been answered.
DRAFT	Indicates that this Message is a draft.
FLAGGED	No defined semantics. Clients can use this flag to mark a message in some user-defined manner.
RECENT	This Message is newly arrived in this Folder. This flag is set when the message is first delivered into the folder and cleared when the containing folder is closed. Clients cannot set this flag.
SEEN	Marks a message that has been opened. A Client sets this flag implicitly when the message contents are retrieved.
DELETED	Allows undoable message deletion. Setting this flag for a message marks it 'deleted' but does not physically remove the message from its folder. The client calls expunge() on a folder to remove all deleted messages in that folder.

Note that a Folder is not guaranteed to support either standard system flags or arbitrary user flags. The getPermanentFlags() method in a Folder returns a Flags object that contains all the system flags supported by that Folder implementation. The presence of the special USER flag indicates that the client can set arbitrary user-definable flags on any Message belonging to this folder.

4.6 Message Creation And Transmission

Message is an abstract class, so an appropriate subclass must be instantiated to create a new Message object. A client creates a message by instantiating an appropriate Message subclass.

For example, the MimeMessage subclass handles Internet email messages. Typically, the client application creates an email message by instantiating a MimeMessage object, and passing required attribute values to that object. In an email message, the client defines Subject, From, and To attributes. The client then passes

message content into the `MimeMessage` object by using a suitably configured `DataHandler` object. See “Message Composition” for details.

After the `Message` object is constructed, the client calls the `Transport.send()` method to route it to its specified recipients. See “Transport Protocols and Mechanisms” for a discussion of the Transport process.

5

The Mail Session

A mail Session object manages the configuration options and user authentication information used to interact with messaging systems.

The JavaMail API supports simultaneous multiple sessions. Each session can access multiple message stores and transports. Any desktop application that needs to access the current primary message store can share the default session. Typically the mail-enabled application establishes the default session, which initializes the authentication information necessary to access the user's Inbox folder. Other desktop applications then use the default session when sending or accessing mail on behalf of the user. When sharing the session object, all applications share authentication information, properties, and the rest of the state of the object.

For example:

A Session object is created using a static factory method:

```
Session session = Session.getInstance(props, authenticator);
```

to create an unshared session, or to access the default session.

```
Session defaultSession =  
    Session.getDefaultInstance(props, authenticator);
```

The Properties object that initializes the Session contains default values and other configuration information. It is expected that clients using the APIs set the values for the listed properties, especially mail.store.protocol, mail.transport.protocol, mail.host, mail.user, and mail.from, since the defaults are unlikely to work in all cases. See Appendix A, "Environment Properties" for a list of properties used by the JavaMail APIs and their defaults.

Some messaging system implementations can use additional properties. Typically the properties object contains user-defined customizations in addition to system-wide defaults. Mail-enabled application logic determines the appropriate set of properties. Lacking a specific requirement, the application can use the system properties object retrieved from `System.getProperties()`.

The Authenticator object controls security aspects for the session object. The messaging system uses it as a callback mechanism to interact with the user when a password is required to login to a messaging system. It also indirectly controls access to the default session, as described below.

Clients using JavaMail can register PasswordAuthentication objects with the Session object for use later in the session, or for use by other users of the same session. Because PasswordAuthentication objects contain passwords, access to this information must be carefully controlled. Applications that create Session objects must restrict access to those objects appropriately. In addition, the Session class shares some responsibility for controlling access to the default session object.

The first call to `getDefaultInstance()` creates a new Session object and associates it with the Authenticator object. Subsequent calls to `getDefaultInstance()` compare the Authenticator object passed in with the Authenticator object saved in the default session. Access to the default session is allowed if both objects have been loaded by the same class loader. Typically, this is the case when both the default session creator and the program requesting default session access are in the same "security domain." Also, if both objects are null, access is allowed. Using null to gain access is discouraged, because this allows access to the default session from any security domain.

A mail-enabled client uses the Session object to retrieve a Store or Transport object in order to read or send mail. Typically, the client retrieves the default Store or Transport object, based on properties loaded for that session:

```
Store store = session.getStore();
```

The client can override the session defaults and access a Store or Transport that implements a particular protocol.

```
Store store = session.getStore("imap");
```

See "*The Provider Registry*" for details.

Implementors of Store and Transport objects will be told the session to which they have been assigned. They can then make the Session object available to other objects contained within this Store or Transport using application-dependent logic.

5.1 The Provider Registry

The Provider Registry allows providers to register their protocol implementations to be used by JavaMail APIs. It provides a mechanism for the discovery of available protocol, for registering new protocols, and for specifying default implementations.

5.1.1 Resource Files

The providers for JavaMail APIs are configured using the following files:

- `javamail.providers` and `javamail.default.providers`
- `javamail.address.map` and `javamail.default.address.map`

Each resource file `javamail.X` is searched in the following order:

1. <java.home>/lib/javamail.X
2. META-INF/javamail.X
3. META-INF/javamail.default.X

Method 1 allows the user to include their own version of the resource file by placing it in the *lib* directory of wherever the `java.home` property points. Method 2 allows an application that uses the JavaMail APIs to include their own resource files in their application's or jar file's META-INF directory. The default files, `javamail.default.X`, are part of the JavaMail `mail.jar` file.

File location depends upon how the `ClassLoader.getResource()` method is implemented. Usually, `getResource()` searches through `CLASSPATH` until it finds the requested file and then stops. JDK 1.1 has a limitation that the number of files of each type that will be found in the `CLASSPATH` is limited to one. However, this only affects method 2 above; method 1 is loaded from a specific location (if allowed by the `SecurityManager`) and method 3 uses a different name to ensure that the default resource file is always loaded successfully.

The ordering of entries in the resource files matters. If multiple entries exist, the first entries take precedence over the latter entries as the initial defaults. For example, the first IMAP provider found will be initially set as the default imap implementation until explicitly changed by the application.

The user- or system-supplied resource files augment, not override, the default files included with the JavaMail APIs. This means that all the entries in all the files loaded will be available.

5.1.1.1 javamail.providers and javamail.default.providers

These resource files specify the stores and transports that are available on the system, allowing an application to "discover" what store and transport implementations are available. The protocol implementations are listed one per line. The file format defines four attributes that describe a protocol implementation. Each attribute is a "="-separated name-value pair with the name in lowercase. Each name-value pair is semi-colon ";" separated.

<code>protocol</code>	Name assigned to protocol. For example, 'smtp' for Transport.
<code>type</code>	Valid entries currently are "store" and "transport"
<code>class</code>	Class name that implements this protocol.
<code>vendor</code>	Optional string identifying the vendor.
<code>version</code>	Optional string identifying the version.

Here's an example of `META-INF/javamail.default.providers` file contents:

```
protocol=imap; type=store; class=com.sun.mail.imap.IMAPStore; vendor=SunMicrosystems, Inc;
protocol=smtp; type=transport; class=com.sun.mail.smtp.SMTPTransport;
```

5.1.1.2 `javamail.address.map` and `javamail.default.address.map`

These resource files map transport address types to the transport protocol. Recall that the `javax.mail.Address.getType()` method returns the address type. The `javamail.address.map` file maps the transport type to the protocol. The file format is a series of name-value pairs. Each key name should correspond to an address type that is currently installed on the system; there should also be an entry for each `javax.mail.Address` implementation that is present if it is to be used. For example, `javax.mail.internet.InternetAddress.getType()` returns `rfc822`. Each referenced protocol should be installed on the system. For the case of `news` below, the client should install a Transport provider supporting the `nntp` protocol.

Here are the typical contents of a `javamail.address.map` file.

```
rfc822=smtp
news=nntp
```

5.1.2 Provider

Provider is a class that describes a protocol implementation. The values come from the `javamail.providers` and `javamail.default.providers` resource files.

5.1.3 Protocol Selection and Defaults

The constructor for the Session object initializes the appropriate variables from the resource files. The order of the protocols in the resource files determines the initial defaults for protocol implementations. The methods, `getProviders()` and `{get, set}Provider()`, allow the client to discover the available (installed) protocol implementations, and to set the protocols to be used by default.

At runtime, an application may set the default implementation to use for a particular protocol. It can set the `mail.protocol.class` property when it creates the Session object. This property specifies the class to use for a particular protocol. The `getProvider()` method consults this property first.

The code can also call `setProviders()` passing in a Provider that was returned by the discovery methods. A Provider object cannot be explicitly created; it must be retrieved using the `getProviders()` method.

In either case, the provider specified must be one of the ones configured in the resource files. Note that the methods described here allow the client to **choose** from among preconfigured implementations, and not to configure a new implementation.

5.1.4 Example Scenarios

Scenario 1: The client application invokes the default protocols:

```
class Application1 {
    init() {

        // application properties include the JavaMail
        // required properties: mail.store.protocol,
        // mail.transport.protocol, mail.host, mail.user

        Properties props = loadApplicationProps();
        Session session = Session.getInstance(props, null);

        // get the store implementation of the protocol
        // defined in mail.store.protocol; the implementation
        // returned will be defined by the order of entries in
        // javamail.providers & javamail.default.providers

        try {
            Store store = session.getStore();
            store.connect();

        } catch (MessagingException mex) {}
        ...
    }
}
```

Scenario 2: The client application presents available implementations to the user and then sets the user's choice as the default implementation:

```
class Application2 {
    init() {

        // application properties include the JavaMail
        // properties: mail.store.protocol,
        // mail.transport.protocol, mail.host, mail.user

        Properties props = loadApplicationProps();
        Session session = Session.getInstance(props, null);

        // find out which implementations are available

        Provider[] providers = session.getProviders();
```

```

// ask the user which implementations to use
// user's response may include a number of choices,
// i.e. imap & nntp store providers & smtp transport

Provider[] userChosenProviders =
askUserWhichProvidersToUse(providers);

// set the defaults based on users response

for (int i = 0; i < userChosenProviders.length; i++)
    session.setProvider(userChosenProviders[i]);

// get the store implementation of the protocol
// defined in mail.store.protocol; the implementation
// returned will be the one configured previously

try    {
        Store store = session.getStore();
        store.connect();

    } catch (MessagingException mex) {}
        ...
    }
}

```

Scenario 3 Application wants to specify an implementation for a given protocol:

```

class Application3 {
    init() {

        // application properties include the JavaMail
        // required properties: mail.store.protocol,
        // mail.transport.protocol, mail.host, mail.user

        Properties props = loadApplicationProps();

        // hard-code an implementation to use
        // "com.acme.SMTPTRANSPORT"

        props.put("mail.smtp.class", "com.acme.SMTPTRANSPORT");
        Session session = Session.getInstance(props, null);

        // get the smtp transport implementation; the
        // implementation returned will be com.acme.SMTPTRANSPORT
        // if it was correctly configured in the resource files.
        // If com.acme.SMTPTRANSPORT can't be loaded, a
        // MessagingException is thrown.
    }
}

```

```

        try {
            Transport transport = session.getTransport("smtp");
        } catch (MessagingException mex) {
            quit();
        }
    }
    ...
}

```

5.2 Managing Security

The Session class allows messaging system implementations to use the Authenticator object that was registered when the session was created. The Authenticator object is created by the application and allows interaction with the user to obtain a user name and password. The user name and password is returned in a PasswordAuthentication object. The messaging system implementation can ask the session to associate a user name and password with a particular message store using the setPasswordAuthentication() method. This information is retrieved using the getPasswordAuthentication() method. This avoids the need to ask the user for a password when reconnecting to a Store that has disconnected, or when a second application sharing the same session needs to create its own connection to the same Store.

Messaging system implementations can register PasswordAuthentication objects with the Session object for use later in the session, or for use by other users of the same session. Because PasswordAuthentication objects contain passwords, access to this information must be carefully controlled. Applications that create Session objects must restrict access to those objects appropriately. In addition, the Session class shares some responsibility for controlling access to the default Session object.

The first call to getDefaultInstance() creates a new Session object and associates the Authenticator object with the Session object. Later calls to getDefaultInstance() compare the Authenticator object passed in, to the Authenticator object saved in the default session. If both objects have been loaded by the same class loader, then getDefaultInstance() will allow access to the default session. Typically, this is the case when both the creator of the default session and the code requesting access to the default session are in the same "security domain." Also, if both objects are null, access is allowed. This last case is discouraged because setting objects to null allows access to the default session from any security domain.

In the future, JDK 1.2 security Permissions could control access to the default session. Note that the Authenticator and PasswordAuthentication classes and their use in JavaMail is similar to the classes with the same names provided in the java.net package in JDK 1.2. As new authentication mechanisms are added to the system, new methods can be added to the Authenticator class to request the needed information. The default implementations of these new methods will fail, but new clients that understand these new authentication mechanisms can provide implementations of these methods. New classes other than PasswordAuthentication could be needed to contain the new authentication information, and new methods could be needed in the Session class to store such information. JavaMail design evolution will be patterned after the corresponding JDK classes.

5.3 Store and Folder URLs

To simplify message folder naming and to minimize the need to manage Store and Transport objects, folders can be named using URLNames. URLNames are similar to URLs except they only include the parsing of the URL string. The Session class provides methods to retrieve a Folder object given a URLName:

```
Folder f = session.getFolder(URLName);

// or

Store s = session.getStore(URLName);
;
```

6

Message Storage And Retrieval

This Section describes JavaMail message storage facilities supported by the Store and Folder classes.

Messages are contained in Folders. New messages are usually delivered to folders by a transport protocol or a delivery agent. Clients retrieve messages from folders using an access protocol.

6.1 The Store Class

The Store class defines a database that holds a Folder hierarchy and the messages within. The Store also defines the access protocol used to access folders and retrieve messages from folders. Store is an abstract class. Subclasses implement specific message databases and access protocols.

Clients gain access to a Message Store by obtaining a Store object that implements the database access protocol. Most message stores require the user to be authenticated before they allow access. `connect()` performs that authentication.

For many message stores, a host name, user name, and password are sufficient to authenticate a user. The JavaMail API provides a `connect()` method that takes this information as input parameters. Store also provides a default `connect()` method. In either case, the client can obtain missing information from the Session object's properties, or by interacting with the user by accessing the Session's Authenticator object.

The default implementation of the `connect` method in the Store class uses these techniques to retrieve all needed information and then calls the `protocolConnect()` method. The messaging system implementation must provide an appropriate implementation of this method. The messaging system can also choose to directly override the `connect()` method.

By default, Store queries the following properties for the user name and host name:

```
mail.user, or user.name system property, if mail.user is not set  
mail.host
```

These global defaults can be overridden on a per-protocol basis by the properties:

```
mail.<protocol>.user
```

mail.<protocol>.host

Note that Passwords can not be specified using properties.

The Store presents a default namespace to clients. Store implementations can also present other namespaces. The `getDefaultFolder()` method on Store returns the root folder for the default namespace.

Clients terminate a session by calling the `close()` method on the Store object. Once a Store is closed (either explicitly using the `close()` method; or externally, if the Mail server dies), all Messaging components belonging to that Store become invalid. Typically, clients will try to recover from an unexpected termination by calling `connect()` to reconnect to the Store object, and then fetching new Folder objects and new Message objects.

6.1.1 Store Events

Store sends the following events to interested listeners:

ConnectionEvent	Generated when a connection is successfully made to the Store, or when an existing connection is terminated or disconnected.
StoreEvent	Communicates alerts and notification messages from the Store to the end user. The <code>getMessageType()</code> method returns the event type, which can be one of: ALERT or NOTICE. The client must display ALERT events in some fashion that calls the user's attention to the message.
FolderEvent	Communicates changes to any folder contained within the Store. These changes include creation of a new Folder, deletion of an existing Folder, and renaming of an existing Folder.

6.2 The Folder Class

The Folder class represents a folder containing messages. Folders can contain subfolders as well as messages, thus providing a hierarchical structure. The `getType()` method returns whether a Folder can hold subfolders, messages, or both. Folder is an abstract class. Subclasses implement protocol-specific Message Folders.

The `getDefaultFolder()` method for the corresponding Store object returns the root folder of a user's default folder hierarchy. The `list()` method for a Folder returns all the subfolders under that folder. The `getFolder(String name)` method for a Folder returns the named subfolder. Note that this subfolder need not exist physically in the Store. The `exists()` method in a folder indicates whether this folder exists. A folder is created in the Store by invoking its `create()` method.

A closed folder allows certain operations; they include deleting the folder, renaming the folder, listing

subfolders, creating subfolders and monitoring for new messages. The `open()` method opens a Folder. All Folder methods except `open()`, `delete()`, and `renameTo()` are valid on an open Folder. Note that the `open()` method is applicable only on Folders that can contain messages.

The messages within a Folder are sequentially numbered, from 1 through the total number of messages. This ordering is referred to as the "mailbox order" and is usually based on the arrival time of the messages in the folder. As each new message arrives into a folder, it is assigned a sequence number that is one higher than the previous number of messages in that folder. The `getMessageNumber()` method on a Message returns its sequence number.

The sequence number assigned to a Message is valid within a session, but only as long as it retains its relative position within the Folder. Any change in message ordering can change the Message object's sequence number. Currently this occurs when the client calls `expunge()` to remove deleted messages and renumber messages remaining in the folder.

A client can reference a message stored within a Folder either by its sequence number, or by the corresponding Message object itself. Since a sequence number can change within a session, it is preferable to use Message objects rather than sequence numbers as cached references to messages. Clients extending JavaMail are expected to provide light-weight Message objects that get filled "on-demand", so that calling `getMessages()` on a Folder object is an inexpensive operation - both in terms of CPU cycles and memory. For instance, an IMAP implementation could return Message objects that contain only the corresponding IMAP UIDs.

6.2.1 The FetchProfile Method

The Message objects returned by a Folder are expected to be light-weight objects. Invoking `getxxx()` methods on a Message cause the corresponding data items to be loaded into the object, on demand. Certain Store implementations support batch fetching of data items for a range of Messages. Clients can use such optimizations, for example, when filling the header-list window for a range of messages. The `FetchProfile()` method allows a client to list the items it will fetch in a batch, for a certain message range.

The following code illustrates the use of `FetchProfile()` when fetching Messages from a Folder. The client fills its header-list window with the Subject, From, and X-mailer headers for all messages in the folder.

```
Message[] msgs = folder.getMessages();
FetchProfile fp = new FetchProfile();
fp.add(FetchProfile.Item.ENVELOPE);
fp.add("X-mailer");
folder.fetch(msgs, fp);
for (int i = 0; i < folder.getMessageCount(); i++) {
    display(msg[i].getFrom());
    display(msg[i].getSubject());
    display(msg[i].getHeader("X-mailer"));
}
```

6.2.2 Folder Events

Folders generate events to notify listeners of any change in either the folder or in its Messages list. The client can register listeners to a closed Folder, but the notification event fires only after that folder is opened.

Folder supports the following events:

ConnectionEvent	<p>This event fires when a Folder is opened or closed.</p> <p>When a Folder closes (either because the client has called <code>close()</code> or from some external cause), all Messaging components belonging to that Folder become invalid. Typically, clients will attempt to recover by reopening that Folder, and then fetching Message objects.</p>
FolderEvent	<p>This event fires when the client creates, deletes or renames this folder. Note that the Store object containing this folder can also fire this event.</p>
MessageCountEvent	<p>This event notifies listeners that the message count has changed. The following actions can cause this change:</p> <ul style="list-style-type: none">• Addition of new Messages into the Folder, either by a delivery agent or because of an <code>append()</code> operation. The new Message objects are included in the event.• Removal of existing messages from this Folder. Removed messages are referred to as expunged messages. The <code>isExpunged()</code> method on removed Messages returns true and the <code>getMessageNumber()</code> method returns the original sequence number assigned to that message. All other Message methods throw a <code>MessageRemovedException</code>. See “The Folder Class” for a discussion of removal of deleted messages in shared folders. The expunged Message objects are included in the event. An expunged message is invalid and should be pruned from the client's view as early as possible. See “The Expunge Process” for details on the <code>expunge()</code> method.

6.2.3 The Expunge Process

Deleting messages from a Folder is a two-phase operation. Setting the **DELETED** flag on messages marks them as deleted, but it does not remove them from the Folder. The deleted messages are removed only when

the client invokes the `expunge()` method on that Folder. The Folder then notifies listeners by firing an appropriate `MessageEvent`. The `MessageEvent` contains the expunged `Message` objects. Note that the `expunge()` method also returns the expunged `Message` objects. The Folder also renumbers the messages falling after the expunged messages in the message list. Thus, when the `expunge()` method returns, the sequence number of those `Message` objects will change. Note, however, that the expunged messages still retain their original sequence numbers.

Since expunging a folder can remove some messages from the folder and renumber others, it is important that the client synchronize itself with the expunged folder as early as possible. The next Sections describe a set of recommendations for clients wanting to expunge a Folder:

- Expunge the folder; close it; and then reopen and refetch messages from that Folder. This ensures that the client was notified of the updated folder state. In fact, the client can just issue the `close()` method with the `expunge` parameter set to true to force an expunge of the Folder during the close operation, thus even avoiding the explicit call to `expunge()`.
- The previous solution might prove to be too simple or too drastic in some circumstances. This paragraph describes the scenario of a more complex client expunging a single access folder; for example, a folder that allows only one read-write connection at a time. The recommended steps for such a client after it issues the `expunge()` command on the folder are:
- Update its message count, either by decrementing it by the number of expunged messages, or by invoking the `getMessageCount()` method on the Folder.
- If the client uses sequence numbers to reference Messages, it must account for the renumbering of Messages subsequent to the expunged messages. Thus if a Folder has 5 messages as shown below, (sequence numbers are within parenthesis), and if the client is notified that Messages A and C are removed, it should account for the renumbering of the remaining Messages as shown in the second figure.

A (1)	B (2)	C (3)	D (4)	E (5)
-------	-------	-------	-------	-------

B (1)	D (2)	E (3)
-------	-------	-------

- The client should prune expunged messages from its internal storage as early as possible.
- The Expunge process becomes complex when dealing with a shared folder that can be edited. Consider the case where two clients are operating on the same folder. Each client possesses its own Folder object, but each Folder object actually represents the same physical folder.

If one client expunges the shared folder, any deleted messages are physically removed from the folder. The primary client can probably deal with this appropriately since it initiated this process and is ready to handle the consequences. However, secondary clients are not guaranteed to be in a state where they can handle an

unexpected Message removed event-- especially if the client is heavily multithreaded or if it uses sequence numbers.

To allow clients to handle such situations gracefully, the JavaMail API applies following restrictions to Folder implementations:

- A Folder can remove and renumber its Messages only when it is explicitly expunged using the `expunge()` method. When the folder is implicitly expunged, it marks any expunged messages as expunged, but it still maintains access to those Message objects. This means that the following state is maintained when the Folder is implicitly expunged:
- `getMessages()` returns expunged Message objects together with valid message objects. However; an expunged message can throw the `MessageExpungedException` if direct access is attempted.
- The messages in the Folder should not be renumbered.
- The implicit expunge operation can not change the total Folder message count.

A Folder can notify listeners of 'implicit' expunges by generating appropriate `MessageEvents`. However, the `removed` field in the event must be set to `false` to indicate that the message is still in the folder. When this Folder is explicitly expunged, then the Folder must remove all expunged messages, renumber it's internal Message cache, and generate `MessageEvents` for all the expunged messages, with each `removed` flag set to `true`.

The recommended set of actions for a client under the above situation is as follows:

- Multithreaded clients that expect to handle shared folders are advised not to use sequence numbers.
- If a client receives a `MessageEvent` indicating message removal, it should check the `removed` flag. If the flag is `false`, it can issue an `expunge()` request on the Folder object to synchronize it with the physical folder. It may also mark the expunged messages in order to notify the end-user.
- If the `removed` flag was set to `true`, the client should follow earlier recommendations on dealing with explicit expunges.

6.3 The Search Process

Search criteria are expressed as a tree of search-terms, forming a parse tree for the search expression. The `SearchTerm` class represents search terms. This is an abstract class with a single method:

```
public boolean match(Message msg);
```

Subclasses implement specific matching algorithms by implementing the `match()` method. Thus new search terms and algorithms can be easily introduced into the search framework by writing the required Java code.

The search package provides a set of standard search terms that implement specific match criteria on Message objects. For example, `SubjectTerm` pattern-matches the given String with the subject header of the

given message.

```
public final class SubjectTerm extends StringTerm {
    public SubjectTerm(String pattern);
    public boolean match(Message m);
}
```

The search package also provides a set of standard logical operator terms that can be used to compose more complex search terms. These include `AndTerm`, `OrTerm` and `NotTerm`.

```
final class AndTerm extends SearchTerm {
    public AndTerm(SearchTerm t1, SearchTerm t2);
    public boolean match(Message msg) {
        // The AND operator
        for (int i=0; i < terms.length; i++)
            if (!terms[i].match(msg))
                return false;
        return true;
    }
}
```

The `Folder` class supports searches on messages through these `search()` method versions:

```
public Message[] search(SearchTerm term)
public Message[] search(SearchTerm term, Message[] msgs)
```

These methods return the `Message` objects matching the specified search `Term`. The default implementation applies the search term on each `Message` object in the specified range. Other implementations may optimize this; for example, the `IMAP Folder` implementation maps the search `Term` into an `IMAP SEARCH` command that the server executes.

7

The JavaBeans Activation Framework

JavaMail relies heavily on the JavaBeans Activation Framework (JAF) to determine the MIME data type, to determine the commands available on that data, and to provide a software component corresponding to a particular behavior. The JAF specification is part of the "Glasgow" JavaBeans specification. More details can be obtained from <http://java.sun.com/beans/glasgow/jaf.html>

This section explains how the JavaMail and JAF APIs work together to manage message content. It describes how clients using JavaMail can access and operate on the content of Messages and BodyParts. This discussion assumes you are familiar with the JAF specification posted at <http://java.sun.com>.

7.1 Accessing the Content

For a client using JavaMail, arbitrary data is introduced to the system in the form of mail messages. The `javax.mail.Part` interface allows the client to access the content. Part consists of a set of attributes and a "content". The Part interface is the common base interface for Messages and BodyParts. A typical mail message has one or more body parts, each of a particular MIME type.

Anything that deals with the content of a Part will use the Part's DataHandler. The content is available through the DataHandlers either as an `InputStream` or as a Java Object. The Part also defines convenience methods that call through to the DataHandler. For example; `Part.getContent()` is the same as `Part.getDataHandler().getContent()` and `Part.getInputStream()` is the same as `Part.getDataHandler().getInputStream()`.

The content returned (either via an `InputStream` or a Java Object) depends on the MIME type. For example; a Part that contains a picture (GIF) returns the following:

- `Part.getContentType()`, returns `image/gif`
- `Part.getInputStream()`, returns an `InputStream` with the bytes of the GIF image as the stream
- `Part.getContent()`, returns a `java.awt.Image` object

When an `InputStream` is returned, any mail-specific encodings are decoded before this stream is returned.

As a java object - using the `getContent()` method. This method returns the content as a Java object. The returned object depends upon the content itself. In the JavaMail API, any Part with a main content type of "multipart/" (any kind of multipart) should return a `javax.mail.Multipart` object from `getContent()`. A Part with a content type of `message/rfc822` returns a `javax.mail.Message` object from `getContent()`.

7.1.1 Example: Message Output

This example shows how you can traverse Parts and display the data contained in the message.

```
public void printParts(Part p) {  
  
    Object o = p.getContent();  
    if (o instanceof String) {  
        System.out.println("This is a String");  
        System.out.println((String)o);  
    } else if (o instanceof Multipart) {  
        System.out.println("This is a Multipart");  
        Multipart mp = (Multipart)o;  
        int count = mp.getCount();  
        for (int i = 0; i < count; i++) {  
            printParts(mp.getBodyPart(i));  
        }  
    } else if (o instanceof InputStream) {  
        System.out.println("This is just an input stream");  
        InputStream is = (InputStream)o;  
        int c; //  
        while ((c = is.read()) != -1)  
            System.out.write(c);  
    }  
}
```

7.2 Operating on the Content

The `DataHandler` allows clients to discover the operations available on the content of a `Message`, and to instantiate the appropriate `JavaBeans` to perform those operations. The most common operations on `Message` content are *view*, *edit* and *print*.

7.2.1 Example: Viewing a Message

Consider a `Message "Viewer"` Bean, that presents a user interface that displays a mail message. This example shows how a viewer bean can be used to display the content of a message (that usually is `text/plain`, `text/html`, or `multipart/mixed`).

Note – Perform error checking to ensure that a valid Component was created.

```
// message passed in as parameter
void setMessage(Message msg) {
    DataHandler dh = msg.getDataHandler();
    CommandInfo cinfo = dh.getCommand("view");
    Component comp = dh.getBean(cinfo);
    this.setMainViewer(comp);
}
```

7.2.2 Example: Showing Attachments

In this example, the user has selected an attachment and wishes to display it in a separate dialog. The client locates the correct viewer object as follows.

```
// Retrieve the BodyPart from the current attachment
BodyPart bp = getSelectedAttachment();

DataHandler dh = bp.getDataHandler();
CommandInfo cinfo = dh.getCommand("view");
Component comp = dh.getBean(cinfo);

// Add viewer to dialog Panel
MyDialog myDialog = new MyDialog();
myDialog.add(viewer);

// display dialog on screen
myDialog.show();
```

See “Setting Message Content” for examples that construct a message for a *send* operation.

7.3 Adding Support for Content Types

Support for commands acting on message data is an implementation task left to the client. JavaMail and JAF APIs intend for this support to be provided by a JAF-Aware JavaBean. Almost all data will require *edit* and *view* support.

Currently, the JavaMail API does not provide *viewer* JavaBeans. The JAF does provide two very simple JAF-aware viewer beans: A Text Viewer and Image Viewer. These beans handle data where content-type has been set to `text/plain` or `image/gif`.

Developers writing a JavaMail client need to write additional viewers that support some of the basic content types-- specifically *message/rfc822*, *multipart/mixed*, and *text/plain*. These are the usual content-types encountered when displaying a Message, and they provide the look and feel of the application.

Content developers providing additional data types should refer to the JAF specification, that discusses how to create `DataContentHandlers` and Beans that operate on those contents.

8

Message Composition

This Section describes the process used to instantiate a message object, add content to that message, and send it to its intended list of recipients.

The JavaMail API allows a client program to create a message of arbitrary complexity. Messages are instantiated from the Message subclass. The client program can manipulate any message as if it had been retrieved from a Store.

8.1 Building a Message Object

To create a message, a client program instantiates a Message object, sets appropriate attributes, and then inserts the content.

- The attributes specify the message address and other values necessary to send, route, receive, decode and store the message. Attributes also specify the message structure and data content type.
- Message content is carried in a DataHandler object, that carries either data or a Multipart object. A DataHandler carries the content body and provides methods the client uses to handle the content. A Multipart object is a container that contains one or more Bodypart objects, each of which can in turn contain DataHandler objects.

8.2 Message Creation

`javax.mail.Message` is an abstract class that implements the Part interface. Therefore, to create a message object, select a message subclass that implements the appropriate message type.

For example, to create a Mime message, a JavaMail client instantiates an empty `javax.mail.internet.MimeMessage` object passing the current Session object to it:

```
Message msg = new MimeMessage(session);
```

8.3 Setting Message Attributes

The Message class provides a set of methods that specify standard attributes common to all messages. The MimeMessage class provides additional methods that set MIME-specific attributes. The client program can also set non-standard attributes (custom headers) as name-value pairs.

The methods for setting standard attributes are listed below:

```
public class Message {
    public void setFrom(Address addr);
    public void setFrom(); // retrieves from system
    public void setRecipients(RecipientType type, Address[]
    addrs);
    public void setReplyTo(Address[] addrs);
    public void setSentDate(Date date);
    public void setSubject(String subject);
    ...
}
```

The Part interface specifies the following method, that sets custom headers:

```
public void setHeader(String name, String value)
```

The `setRecipients()` method takes a `RecipientType` as its first parameter, which specifies which recipient field to use. Currently, `Message.RecipientType.TO`, `Message.RecipientType.CC`, and `Message.RecipientType.BCC` are defined. Additional `RecipientTypes` may be defined as necessary.

The `Message` class provides two versions of the of the `setFrom()` method:

- `setFrom(Address addr)` specifies the sender explicitly, from an `Address` object parameter.
- `setFrom()` retrieves the sender's username from the local system.

The code sample below sets attributes for the `MimeMessage` just created. First, it instantiates address objects to be used as 'To' and 'From' addresses. Then, it calls 'set' methods, which equate those addresses to appropriate message attributes.

```
Address toAddrs[] = new InternetAddress[1];
toAddrs[0] = new InternetAddress("luke@rebellion.gov");
Address fromAddr =
    new InternetAddress("han.solo@smuggler.com");

msg.setFrom(fromAddr);
msg.setRecipients(Message.RecipientType.TO, addrs);
msg.setSubject("Takeoff time.");
msg.setSentDate(new Date());
```

8.4 Setting Message Content

The `Message` object carries content data within a `DataHandler` object. To add content to a `Message`, a client creates content, instantiates a `DataHandler` object, places content into that `DataHandler` object, and places that object into a `Message` object that has had its attributes defined.

The JavaMail API provides two methods that set message content. The first method uses the `setDataHandler()` method. The second method uses the `setContent()` method.

Typically, clients add content to a `DataHandler` object by calling `setDataHandler(DataHandler)` on a `Message` object. The `DataHandler` is an object that encapsulates data. The data is passed to the `DataHandler`'s constructor as either a `DataSource` (a stream connected to the data) or as a Java object. The `InputStream` object creates the `DataSource`. See “The JavaBeans Activation Framework” for additional information.

```
public class DataHandler {
    DataHandler(DataSource dataSource);
    DataHandler(Object data, String mimeType);
}
```

The code sample below shows how to place text content into an `InternetMessage`. First, create the text as a string object. Then, pass the string into a `DataHandler` object, together with its MIME type. Finally, add the `DataHandler` object to the message object:

```
// create brief message text
String content = "Leave at 300.";

// instantiate the DataHandler object

DataHandler data = new DataHandler(content, "text/plain");

// Use setDataHandler() to insert data into the
// new Message object

msg.setDataHandler(data);
```

Alternately, `setContent()` implements a simpler technique, that takes the data object and its MIME type. `setContent()` creates the `DataHandler` object automatically:

```
// create the message text
String content = "Leave at 300.";

// call setContent to pass content and content type
// together into the message object

msg.setContent(content, "text/plain");
```

When the client calls `Transport.send()` to send this message, the recipient will receive the message below, using either technique:

Date: Wed, 23 Apr 1997 22:38:07 -0700 (PDT)
From: han.solo@smuggler.com
Subject: Takeoff time
To: luke@rebellion.gov

Leave at 300.

8.5 Building a MIME Multipart Message

Follow these steps to create a MIME Multipart Message:

1. Instantiate a new `MimeMultipart` object, or a subclass.
2. Create `MimeBodyParts` for the specific message parts. Use `setContent()` or `setDataHandler()` to create the content for each `Bodypart`, as described in the previous section.

Note – The default subtype for a `MimeMultipart` object is *mixed*. It can be set to other subtypes as required. `MimeMultipart` subclasses might already have their subtype set appropriately.

3. Insert the Multipart object into the Message object by calling `setContent(Multipart)` within a newly-constructed Message object.

The example below creates a Multipart object and then adds two message parts to it. The first message part is a text string “Spaceport Map,” and the second contains a document of type “application/postscript.” Finally, this multipart object is added to a `MimeMessage` object of the type described above.

```
// Instantiate a Multipart object
MimeMultipart mp = new MimeMultipart();

// create the first bodypart object
MimeBodyPart b1 = new MimeBodyPart();

// create textual content
// and add it to the bodypart object
b1.setContent("Spaceport Map", "text/plain");
mp.addBodyPart(b1);
```

```

// Multipart messages usually have more than
// one body part. Create a second body part
// object, add new text to it, and place it
// into the multipart message as well. This
// second object holds postscript data.

MimeBodyPart b2 = new MimeBodyPart();
b2.setContent(map, "application/postscript");
mp.addBodyPart(b2);

// Create a new message object as described above,
// and set its attributes. Add the multipart
// object to this message and call saveChanges()
// to write other message headers automatically.

Message msg = new MimeMessage(session);

// Set message attributes as in a singlepart
// message.

msg.setContent(mp);           // add Multipart
msg.saveChanges();           // save changes

```

After all message parts are created and inserted, call `saveChanges()` to ensure that the client writes appropriate message headers. This is identical to the process followed with a single part message. Note that the JavaMail API calls `saveChanges()` implicitly during the `send()` process, so invoking it is unnecessary and expensive if the message is to be sent immediately.

Transport Protocols and Mechanisms

The Transport abstract class defines the message submission and transport protocol. Transport subclasses implement SMTP and other transport protocols.

9.1 Obtaining the Transport Object

The Transport object is seldom explicitly created. `getTransport()` obtains a transport object from the Session factory. The JavaMail API provides three versions of `getTransport()`:

```
public class Session {
    public Transport getTransport(Address address);
    public Transport getTransport(String protocol);
    public Transport getTransport();
}
```

- `getTransport(Address address)` returns the implementation of the transport class based on the address type. A user-extensible map defines which transport type to use for a particular address. For example, if the address is an `InternetAddress`, and `InternetAddress` is mapped to a protocol that supports SMTP, then `SMTPTransport` can be returned.
- The client can also call `getTransport("SMTP")` to request SMTP, or another transport implementation protocol.
- `getTransport()` returns the transport specified in the `mail.transport.protocol` property.

See “The Mail Session” for details.

9.1.1 Transport Methods

The Transport class provides `connect()` and `protocolConnect()` methods, which operate similarly to those on the Store class. See “The Store Class” for details.

Transport fires a `ConnectionEvent` to notify its listeners of a successful or a failed connection. Transport can throw an `IOException` if the connection fails.

Transport implementations should ensure that the message specified is of a known type. If the type is known, then the transport object sends the message to its specified destinations. If the type is not known, then the Transport object can attempt to reformat the Message into a suitable version using gatewaying techniques, or it can throw a MessagingException, indicating failure. For example, the SMTP transport implementation recognizes MimeMessages. It invokes the `writeTo()` method on MimeMessage to generate a RFC822 format byte stream that is sent to the SMTP host.

The message is sent using the `Transport.send()` static method or `sendMessage()` instance method. `Transport.send()` is a convenience method that instantiates the transports necessary to send the message, depending on the recipients' addresses, and then passes the message to each transport's `sendMessage()` method. Alternatively, the client can get the transport that implements a particular protocol itself and send the message using the `sendMessage()` method. This adds the benefit of being able to register as event listeners on the individual transports.

Note that the `Address[]` argument passed to the `send()` and `sendMessage()` methods do not need to match the addresses provided in the message headers. Although these arguments usually will match, the end-user actually determines where the messages are actually sent. This is useful for implementing the Bcc: header, and other similar functions.

9.2 Transport Events

Clients can register as listeners for events fired by transport implementations. (Note that the abstract Transport class doesn't fire any events, only particular protocol implementations). There are two events fired: `ConnectionEvent` and `TransportEvent`.

9.2.1 ConnectionEvent

If the transport connects successfully, it will fire the `ConnectionEvent` with the type set to `OPENED`. If the connection times out or is closed, `ConnectionEvent` with type `CLOSED` is fired.

9.2.2 TransportEvent

The `sendMessage()` method fires `TransportEvent` to its listeners that contains information about its success or failure. There are three types of `TransportEvent`: `MESSAGE_DELIVERED`, `MESSAGE_NOT_DELIVERED`, `MESSAGE_PARTIALLY_DELIVERED`. The event contains three arrays of addresses: `validSent[]`, `validUnsent[]` and `invalid[]` that list the valid and invalid addresses for this message and protocol.

MESSAGE_DELIVERED	When the message has been successfully delivered to all recipients by this transport. <code>validSent[]</code> contains all the addresses. <code>validUnsent[]</code> and <code>invalid[]</code> are null
MESSAGE_NOT_DELIVERED	Is null, <code>validUnsent[]</code> may have addresses that are valid. <code>invalid[]</code> may contain invalid addresses.
MESSAGE_PARTIALLY_DELIVERED	Message was successfully sent to some recipients but not to all. <code>validSent[]</code> holds addresses of recipients to whom the message was sent. <code>validUnsent[]</code> holds valid addresses but the message wasn't sent to them. <code>invalid[]</code> holds invalid addresses

9.3 Using The Transport Class

The code segment below sends an `InternetMessage` using a `Transport` class implementing the SMTP protocol. The client creates two `InternetAddresses` that specify the recipients, and retrieves transport object from the default `Session` that supports sending messages to `InternetAddresses`. Then the transport object sends the message.

```
// Get a session
Session session = Session.getInstance(props, null);

// Create an empty MimeMessage and its part
Message msg = new MimeMessage(session);
... add headers and message parts as before

// create two destination addresses
Address[] addrs = {new InternetAddress("mickey@disney.com"),
                  new InternetAddress("goofy@disney.com")};

// get a transport that can handle sending message to
// InternetAddresses. This will probably map to a transport
// that supports SMTP. (See section 5.2)
Transport trans = session.getTransport(addrs[0]);

// add ourselves as ConnectionEvent and TransportEvent listeners
trans.addConnectionListener(this);
```

```
trans.addTransportListener(this);

// connect method determines what host to use from the
// session properties
trans.connect();

// send the message to the addresses we specified above
trans.sendMessage(msg, addrs);
```

10

Internet Mail

The JavaMail specification does not define any implementation. However, the API does include a set of classes that implement Internet Mail standards. Although not part of the specification, these classes can be considered part of the JavaMail package. They show how to adapt an existing messaging architecture to the JavaMail framework.

These classes implement the Internet Mail Standards defined by the RFCs listed below:

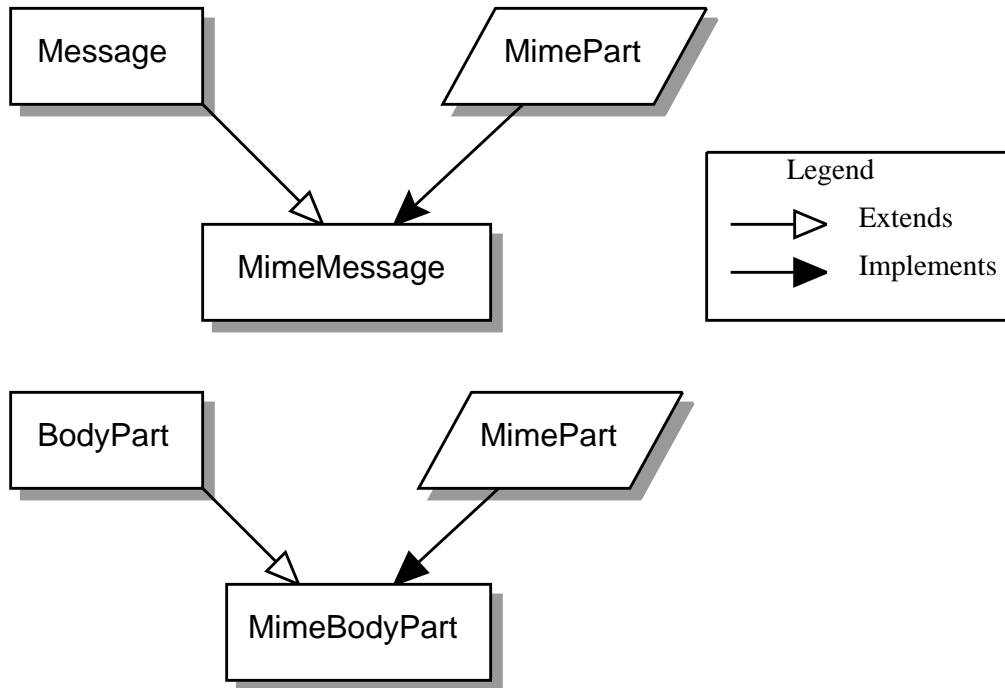

- RFC822 (Standard for the Format of Internet Text Messages)
- RFC2045, RFC2046, RFC2047 (MIME)

RFC822 describes the structure of messages exchanged across the Internet. Messages are viewed as having a header and contents. The header is composed of a set of standard and optional header fields. The header is separated from the content by a blank line. The RFC specifies the syntax for all header fields and the semantics of the standard header fields. It does not however, impose any structure on the message contents.

The MIME RFCs 2045, 2046 and 2047 define message content structure by defining structured body parts, defining a typing mechanism for identifying different media types, and defining a set of encoding schemes to encode data into mail-safe characters.

The Internet Mail package allows clients to create, to use and to send messages conforming to the standards listed above. It gives service providers a set of base classes and utilities they can use to implement Stores and Transports that use the Internet mail protocols. See “MimeMessage Object Hierarchy” for a Mime class and interface hierarchy diagram.

The JavaMail MimePart interface models an *entity* as defined in RFC2045, Section 2.4. MimePart extends the JavaMail Part interface to add MIME-specific methods and semantics. The MimeMessage and MimeBodyPart classes implement the MimePart interface. The following figure shows the class hierarchy of these classes.

10.1 The MimeMessage Class

The `MimeMessage` class extends `Message` and implements `MimePart`. This class implements an email message that conforms to the RFC822 and MIME standards.

`MimeMessage` provides a default constructor that creates an empty `MimeMessage` object. The client can fill the message later by invoking the `parse()` method on an RFC822 input stream. Note that `parse()` is protected, so that only this class and its subclasses are expected to use this method. Service providers implementing 'light-weight' `Message` objects that are filled on demand, can generate the appropriate byte stream and invoke `parse()` when a component is requested from a message. Service providers that can provide a separate byte stream for the message body (distinct from the message header) can override the `getContentStream()` method.

The client can also use the default constructor to create new `MimeMessage` objects for sending. The client sets appropriate attributes and headers, inserts content into the message object, and finally calls the `send()` method for that `MimeMessage` object.

This code sample creates a new `MimeMessage` object for sending. See "Message Composition" and "Transport Protocols and Mechanisms" for details.

```
MimeMessage m = new MimeMessage(session);
```

```

// Set FROM:
m.setFrom(new InternetAddress("jmk@Sun.COM"));
// Set TO:
InternetAddress a[] = new InternetAddress[1];
a[0] = new InternetAddress("javamail@Sun.COM");
m.setRecipients(Message.RecipientType.TO, a);
// Set content
m.setContent(data, "text/plain");
// Send message
m.send();

```

MimeMessage also provides a constructor that uses an input stream to instantiate itself. The constructor internally invokes `parse()` to fill the message. The `InputStream` object is left positioned at the end of the message body.

```

InputStream in = getMailSource(); // a stream of mail
messages
MimeMessage m = null;
for (; ; ) {
    try {
        m = new MimeMessage(session, in);
    } catch (MessagingException ex) {
        // reached end of message stream
        break;
    }
}

```

MimeMessage implements the `writeTo()` method by writing an RFC822-formatted byte stream of its headers and body. This is accomplished in two steps: First, the MimeMessage object writes out its headers; then it delegates the rest to the `DataHandler` object representing the content.

10.2 The MimeBodyPart Class

The `MimeBodyPart` class extends `BodyPart` and implements the `MimePart` interface. This class represents a Part inside a `Multipart`. `MimeBodyPart` implements a Body Part as defined by RFC2045, Section 2.5.

`getBodyPart(int index)` returns the `MimeBodyPart` object at the given index. `MimeMultipart` also allows the client to fetch `MimeBodyPart` objects based on their Content-IDs.

`addBodyPart()` adds a new `MimeBodyPart` object to a `MimeMultipart` as a step towards constructing a new multipart `MimeMessage`.

10.3 The MimeMultipart Class

The `MimeMultipart` class extends `Multipart` and models a MIME multipart content within a message or a body part.

A `MimeMultipart` is obtained from a `MimePart` containing a `ContentType` attribute set to "multipart," by invoking that part's `getContent()` method.

The client creates a new `MimeMultipart` object by invoking its default constructor. To create a new multipart `MimeMessage`, create a `MimeMultipart` object (or its subclass); use set methods to fill the appropriate `MimeBodyParts`; and finally, use `setContent(Multipart)` to insert it into the `MimeMessage`.

`MimeMultipart` also provides a constructor that takes an input stream positioned at the beginning of a MIME multipart stream. This class parses the input stream and creates the child body parts.

The `getSubType()` method returns the multipart message MIME subtype. The subtype defines the relationship among the individual body parts of a multipart message. More semantically complex multipart subtypes are implemented as subclasses of `MimeMultipart`, providing additional methods that expose specific functionality.

Note that a multipart content object is treated like any other content. When parsing a MIME Multipart stream, the JavaMail implementation uses the JAF framework to locate a suitable `DataContentHandler` for the specific subtype and uses that handler to create the appropriate `Multipart` instance. Similarly, when generating the output stream for a `Multipart` object, the appropriate `DataContentHandler` is used to generate the stream.

10.4 The MimeUtility Class

`MimeUtility` is a utility class that provides MIME-related functions. All methods in this class are static methods. These methods currently perform the functions listed below:

10.4.1 Content Encoding and Decoding

Data sent over RFC 821/822-based mail systems are restricted to 7-bit US-ASCII bytes. Therefore, any non-US-ASCII content needs to be encoded into the 7-bit US-ASCII (mail-safe) format. MIME (RFC 2045) specifies the "base64" and "quoted-printable" encoding schemes to perform this encoding. The following methods support content encoding:

- The `getEncoding()` method takes a `DataSource` object and returns the Content-Transfer-Encoding that should be applied to the data in that `Datasource` object to make it mail-safe.
- The `encode()` method wraps an encoder around the given output stream based on the specified Content-Transfer-Encoding. The `decode()` method decodes the given input stream, based on the specified Content-Transfer-Encoding.

10.4.2 Header Encoding and Decoding

RFC 822 restricts the data in message headers to 7bit US-ASCII characters. MIME (RFC 2047) specifies a mechanism to encode non 7bit US-ASCII characters so that they are suitable for inclusion in message headers. This section describes the methods that enable this functionality.

The header-related methods (`getHeader`, `setHeader`) in `Part` and `Message` operate on `Strings`. `String` objects contain (16 bit) Unicode characters.

Since RFC 822 prohibits non US-ASCII characters in headers, clients invoking the `setHeader ()` methods must ensure that the header values are appropriately encoded if they contain non US-ASCII characters.

The encoding process (based on RFC 2047) consists of two steps:

1. Convert the Unicode String into an array of bytes in another charset. This step is required because Unicode is not yet a widely used charset. Therefore, a client must convert the Unicode characters into a charset that is more palatable to the recipient.
2. Apply a suitable encoding format that ensures that the bytes obtained in the previous step are mail-safe.

The `encodeText ()` method combines the two steps listed above to create an encoded header. Note that as RFC 2047 specifies, only "unstructured" headers and user-defined extension headers can be encoded. It is prudent coding practice to run such header values through the encoder to be safe. Also note that `encodeText ()` encodes header values only if they contain non US-ASCII characters.

The reverse of this process (decoding) needs to be performed when handling header values obtained from a `MimeMessage` or `MimeBodyPart` using the `getHeader ()` set of methods, since those headers might be encoded as per RFC 2047. The `decodeText ()` method takes a header value, applies RFC 2047 decoding standards, and returns the decoded value as a Unicode String. Note that this method should be invoked only on "unstructured" or user-defined headers. Also note that `decodeText ()` attempts decoding only if the header value was encoded in RFC 2047 style. It is advised that you always run header values through the decoder to be safe.

10.5 The `ContentType` Class

The `ContentType` class is a utility class that parses and generates MIME content-type headers.

To parse a MIME content-Type value, create a `ContentType` object and invoke the `toString ()` method.

The `ContentType` class also provides methods that match Content-Type values.

The following code fragment illustrates the use of this class to extract a MIME parameter.

```
String type = part.getContentType();
ContentType cType = new ContentType(type);

if (cType.match("application/x-foobar"))
    iString color = "cType.getParameter(color)";
```

This code sample uses this class to construct a MIME Content-Type value:

```
ContentType cType = new ContentType();
```

```
cType.setPrimaryType("application");
cType.setSubType("x-foobar");
cType.setParameter("color", "red");

String contentType = cType.toString();
```

A

Environment Properties

This section lists the environment properties that are used by the JavaMail APIs.

Note that Applets can not determine some defaults listed in this Appendix. When writing an applet, you must specify the properties you require.

Property	Description
mail.store.protocol	Specifies the default Message Access Protocol. The <code>Session.getStore()</code> method returns a <code>Store</code> object that implements this protocol. The protocol can be explicitly specified by using <code>Session.getStore(String protocol)</code> . Defaults to the first appropriate protocol in the config files.
mail.transport.protocol	Specifies the default Transport Protocol. The <code>Session.getTransport()</code> method returns a <code>Transport</code> object that implements this protocol. The client can explicitly specify the protocol by using <code>Session.getTransport(String protocol)</code> .
mail.host	Specifies the default Mail server. The <code>Store</code> and <code>Transport.connect()</code> methods use this property (if the protocol-specific host property is absent) to locate the target host. Defaults to the local machine.

Property	Description
mail.user	Specifies the username provided when connecting to a Mail server. The Store and Transport <code>connect()</code> methods use this property (if the protocol-specific username property is absent) to obtain the username. Defaults to <code>user.name</code> .
mail.<protocol>.host	Specifies the protocol-specific default Mail server. This overrides the <code>mail.host</code> property.
mail.<protocol>.user	Specifies the protocol-specific default username for connecting to the Mail server. This overrides the <code>mail.user</code> property.
mail.from	Specifies the return address of the current user. Used by the <code>InternetAddress.getLocalAddress()</code> method to specify the current user's email address. Defaults to <code>"username@host"</code>

B

Examples Using the Mail API

Following are some example programs that illustrate the use of the Java Mail APIs. These examples are also included in the JavaMail implementation.

B.1 Example: Showing a Message

```
import java.util.*;
import java.io.*;
import javax.mail.*;
import javax.mail.internet.*;

/*
 * Demo app that exercises the Message interfaces.
 * Show information about and contents of messages.
 *
 * msgshow protocol host user password mailbox msgnum
 */

public class showmessage {

    public static void main(String argv[]) {
        try {
            if (argv.length != 6) {
                System.out.println(
                    "usage: msgshow protocol host user password mailbox msgnum");
                System.exit(1);
            }

            boolean debug = false;

            String protocol = argv[0];
            String host = argv[1];
            String user = argv[2];
```

```

String password = argv[3];
String mbox = argv[4]; // mailbox name

// which message number to retrieve
int msgnum = Integer.parseInt(argv[5]);

// Get a Session object
Properties props = System.getProperties();
Session session = Session.getDefaultInstance(props, null);

// Get a Store object
Store store = session.getStore(protocol);
store.connect(host, user, password);

// Open the Folder
Folder folder = store.getDefaultFolder();
if (folder == null) {
    System.out.println("No default folder");
    System.exit(1);
}

folder = folder.getFolder(mbox);
if (folder == null) {
    System.out.println("Invalid folder");
    System.exit(1);
}

folder.open(Folder.READ_WRITE);
int totalMessages = folder.getMessageCount();

int newMessages = folder.getNewMessageCount();
System.out.println("Total messages = " + totalMessages);
System.out.println("New messages = " + newMessages);
System.out.println("-----");

if (msgnum == -1) {
    // Attributes & Flags for all messages ..
    Message[] msgs = folder.getMessages();

    // Use a suitable FetchProfile
    FetchProfile fp = new FetchProfile();
    fp.add(FetchProfile.Item.ENVELOPE);
    fp.add(FetchProfile.Item.FLAGS);
    fp.add("X-Mailer");
    folder.fetch(msgs, fp);

    for (int i = 0; i < msgs.length; i++) {
        System.out.println("-----");
        System.out.println("MESSAGE #" + (i + 1) + ":");
    }
}

```

```

        dumpEnvelope(msgs[i]);
        // dumpPart(msgs[i]);
    }
} else {
    System.out.println("Getting message number: " + msgnum);
    Message m = folder.getMessage(msgnum);

    dumpPart(m);
}

folder.close(false);
store.close();
} catch (Exception ex) {
    ex.printStackTrace();
}
}

public static void dumpPart(Part p) throws Exception {
    if (p instanceof Message)
        dumpEnvelope((Message)p);

    System.out.println("CONTENT-TYPE: " + p.getContentType());

    Object o = p.getContent();
    if (o instanceof String) {
        System.out.println("This is a String");
        System.out.println((String)o);
    } else if (o instanceof Multipart) {
        System.out.println("This is a Multipart");
        Multipart mp = (Multipart)o;
        int count = mp.getCount();
        for (int i = 0; i < count; i++)
            dumpPart(mp.getBodyPart(i));
    } else if (o instanceof InputStream) {
        System.out.println("This is just an input stream");
        InputStream is = (InputStream)o;
        int c;
        while ((c = is.read()) != -1)
            System.out.write(c);
    }
}

public static void dumpEnvelope(Message m) throws Exception {
    Address[] a;

    if ((a = m.getFrom()) != null) {
        for (int j = 0; j < a.length; j++)
            System.out.println("FROM: " + a[j].toString());
    }
}

```

```

if ((a = m.getRecipients(Message.RecipientType.TO)) != null) {
    for (int j = 0; j < a.length; j++)
        System.out.println("TO: " + a[j].toString());
}

System.out.println("SUBJECT: " + m.getSubject());

Date d = m.getSentDate();
System.out.println("SendDate: " +
    (d != null ? d.toString() : "UNKNOWN"));

Flags flags = m.getFlags();
StringBuffer sb = new StringBuffer();
Flags.Flag[] sf = flags.getSystemFlags(); // get the system flags

boolean first = true;
for (int i = 0; i < sf.length; i++) {
    String s;
    Flags.Flag f = sf[i];
    if (f == Flags.Flag.ANSWERED)
        s = "\\Answered";
    else if (f == Flags.Flag.DELETED)
        s = "\\Deleted";
    else if (f == Flags.Flag.DRAFT)
        s = "\\Draft";
    else if (f == Flags.Flag.FLAGGED)
        s = "\\Flagged";
    else if (f == Flags.Flag.RECENT)
        s = "\\Recent";
    else if (f == Flags.Flag.SEEN)
        s = "\\Seen";
    else
        continue; // skip it
    if (first)
        first = false;
    else
        sb.append(' ');
    sb.append(s);
}
String[] uf = flags.getUserFlags(); // get the user flag strings
for (int i = 0; i < uf.length; i++) {
    if (first)
        first = false;
    else
        sb.append(' ');
    sb.append(uf[i]);
}
System.out.println("FLAGS = " + sb.toString());

```

B.2 Example : Listing Folders

```
import java.util.Properties;
import javax.mail.*;

/**
 * Demo app that exercises the Message interfaces.
 * List information about folders.
 */

public class listfolders {
    public static void main(String argv[]) throws Exception {

        String protocol = argv[0];
        String host = argv[1];
        String user = argv[2];
        String password = argv[3];
        String root = argv[4];
        String pattern = argv[5]; // normally "%"
        boolean recursive = Boolean.valueOf(argv[6]).booleanValue();

        // Get a Session object
        Session session = Session.getDefaultInstance(
            System.getProperties(), null);
        session.setDebug(true);

        // Get a Store object
        Store store = session.getStore(protocol);
        store.connect(host, user, password);

        // Open a Folder
        Folder folder = store.getFolder(argv[3]);
        if (folder == null || !folder.exists()) {
            System.out.println("Invalid folder");
            System.exit(1);
        }

        // List namespace
        Folder rf;
        if (root.length() != 0)
            rf = store.getFolder(root);
        else
```

```

        rf = store.getDefaultFolder();
        Folder[] f = rf.list(pattern);
        for (int i = 0; i < f.length; i++)
            dumpFolder(f[i], "", recursive);
    }

    static void dumpFolder(Folder folder, String tab, boolean recurse) throws
    Exception {
        System.out.println(tab + "Name: " + folder.getName());
        System.out.println(tab + "Full Name: " + folder.getFullName());

        if (!folder.isSubscribed())
            System.out.println(tab + "Not Subscribed");

        if (((folder.getType() & Folder.HOLDS_MESSAGES) != 0) &&
            folder.hasNewMessages())
            System.out.println(tab + "Has New Messages");

        if ((folder.getType() & Folder.HOLDS_FOLDERS) != 0) {
            System.out.println(tab + "Is Directory");
            if (recurse) {
                Folder[] f = folder.list();
                for (int i=0; i < f.length; i++)
                    dumpFolder(f[i], tab + "", recurse);
            }
        }
    }
}

```

B.3 Example: Search a Folder for a Message

```

import javax.mail.*;
import javax.mail.internet.*;
import javax.mail.search.*;
import java.util.Date;

/*
 * Search the given folder for messages matching the given
 * criteria.
 */

public class searchmessages {

```

```

public static void main(String argv[]) {

    if (argv.length != 6) {
        System.out.println(
            "Usage: monitor <protocol> <host> <user> <password> <mbox> " +
            "<subject> <from> and|or");
        System.exit(1);
    }

    String protocol = argv[0];
    String host = argv[1];

    sb.append(uf[i]);
}
System.out.println("FLAGS = " + sb.toString());

```

B.4 Example: Monitoring a Mailbox

```
import java.io.*;
import javax.mail.*;
import javax.mail.event.*;

/* Monitors given mailbox for new mail */

public class monitormailbox {

    public static void main(String argv[])
    {
        if (argv.length != 6) {
            System.out.println(
                "Usage: monitor <protocol> <host> <user> <password> <mbox> <freq>");
            System.exit(1);
        }

        String protocol = argv[0];
        String host = argv[1];
        String user = argv[2];
        String password = argv[3];
        String mbox = argv[4];
        String freqarg = argv[5];

        System.out.println("\nTesting monitor\n");
        try {
            // Get a Session object
            Session session = Session.getDefaultInstance(
                System.getProperties(), null);
            session.setDebug(true);

            // Get a Store object
            Store store = session.getStore(protocol);

            // Connect
            store.connect(host, user, password);

            // Open a Folder
            Folder folder = store.getFolder(argv[3]);
            if (folder == null || !folder.exists()) {
                System.out.println("Invalid folder");
            }
        }
    }
}
```

```

        System.exit(1);
    }

    folder.open(Folder.READ_WRITE);

    // Add messageCountListener to listen for new messages
    folder.addMessageCountListener(new MessageCountAdapter() {
        public void messagesAdded(MessageCountEvent ev) {
            Message[] msgs = ev.getMessages();
            System.out.println("Got " + msgs.length + " new messages");

            // Just dump out the new messages
            for (int i = 0; i < msgs.length; i++) {
                try {
                    msgs[i].writeTo(System.out);
                } catch (Exception ex) {
                    ex.printStackTrace();
                }
            }
        }
    });

    // Check mail once in "freq" MILLIseconds
    int freq = Integer.parseInt(freqarg);

    while (true) {
        Thread.sleep(freq); // sleep for freq milliseconds

        // This is to force the IMAP server to send us
        // EXISTS notifications.

        folder.getMessageCount();
    }
} catch (Exception ex) {
    ex.printStackTrace();
}
}
}

```

B.5 Example: Sending a Message

```
import java.util.*;
```

```

import javax.mail.*;
import javax.mail.internet.*;

/**
 * usage: sendmessage to from smtp host multipart
 *
 * Send a simple text/plain message to the "to"
 * address, from the "from" address, using the
 * smtp host as the machine with the smtp server
 * running.
 *
 * if multipart is "true" send a multipart message
 * else if multipart is "false" send a text/plain
 * message.
 */

public class sendmessage {

    public static void main(String[] args) {
        if (args.length != 4) {
            System.out.println(
                "usage: sendmessage <to> <from> <smtp host> <true|false>");
            System.exit(1);
        }

        boolean debug = false; // change to get more information
        String msgText = "A body.\nthe second line.";
        String msgText2 = "Another body.\nmore lines";
        boolean sendmultipart = Boolean.valueOf(args[3]).booleanValue();

        // set the host
        Properties props = new Properties();
        props.put("mail.smtp.host", args[2]);

        // create some properties and get the default Session
        Session session = Session.getDefaultInstance(props, null);
        session.setDebug(debug);

        try {
            // create a message
            Message msg = new MimeMessage(session);

            // set the from
            InternetAddress from = new InternetAddress(args[1]);
            msg.setFrom(from);

            InternetAddress[] address = {new InternetAddress(args[0])};
            msg.setRecipients(Message.RecipientType.TO, address);
            msg.setSubject("JavaMail APIs Test");
        }
    }
}

```

```

if (!sendmultipart) {
    // send a plain text message
    msg.setContent(msgText, "text/plain");
} else {
    // send a multipart message

    // create and fill the first message part
    MimeBodyPart mbp1 = new MimeBodyPart();
    mbp1.setContent(msgText, "text/plain");

    // create and fill the second message part
    MimeBodyPart mbp2 = new MimeBodyPart();
    mbp2.setContent(msgText2, "text/plain");

    // create the Multipart and its parts to it
    Multipart mp = new MimeMultipart();
    mp.addBodyPart(mbp1);
    mp.addBodyPart(mbp2);

    // add the Multipart to the message
    msg.setContent(mp);
}

Transport.send(msg);
} catch (MessagingException mex) {
    mex.printStackTrace();
}
}
}

```

C

Message Security

C.1 Overview

This is not a full specification of how Message Security will be integrated into the JavaMail system. This is a description of implementation strategy. The purpose of this section is to declare that it is possible to integrate message security; not to define how it will be integrated. The final design for Message Security will change based on feedback and finalization of the S/MIME IETF specification.

This section discusses encrypting/decrypting messages, and signing/verifying signatures. It will not discuss how Security Restrictions on untrusted or signed applets will work, nor will it discuss a general authentication model for Stores For example; a GSS API in Java.

C.1.1 Displaying an Encrypted/Signed Message

Displaying an encrypted or signed message is the same as displaying any other message. The client uses the Datahandler for that encrypted message together with the "view" command. This returns a bean which displays the data. There will be both a multipart/signed and multipart/encrypted viewer bean (can be the same bean). The beans will need to be aware of the MultiPartSigned/MultiPartEncrypted classes.

C.1.2 MultiPartEncrypted/Signed Classes

The JavaMail API will probably add two new content classes: MultiPartEncrypted and MultiPartSigned. They subclass the MultiPart class and handle the MIME types multipart/encrypted and multipart/signed. There are many possible "protocols" which specify how the message has been encrypted and/or signed. The MPE/MPS classes will find all the installed protocols. The ContentType's protocol parameter determines which the protocol class to use. There needs to be a standard registration of protocol objects, or a way to search for valid packages and instantiate a particular class. The MultiPart classes will hand off the control information, other parameters, and the data to be manipulated (either the signed/encrypted block) through

some defined Protocol interface.

C.1.3 Reading the Contents

There will be times when an applet/application needs to retrieve the content of the message without displaying its content. The code sample below shows one possible technique, with a message containing encrypted content:

```
Message msg = // message gotten from some folder, or somehow
if (msg.isMimeType("multipart/encrypted")) {
    Object o = msg.getContent();
    if (o instanceof MultiPartEncrypted) {
        MultiPartEncrypted mpe = (MultiPartEncrypted) o;
        mpe.decrypt();
        // use the default keys/certs from the user
        // also, should be able to determine
        // whether or not to interact with the user

        // should then be able to use the multipart methods to
        // get any contained blocks }
    }
}
```

`getContent()` returns a `MultiPartEncrypted` object. There will be methods on this class to decrypt the content. The decryption could either determine which keys needed to be used, or use the defaults (maybe the current user's keys) or could pass in explicitly which keys/certificates to use.

C.1.4 Verifying Signatures

Applications/applets will need to verify the validity of a signature. The code sample below shows how this might be done:

```
Message msg = // message gotten from some folder
if (msg.isMimeType("multipart/signed")) {
    Object o = msg.getContent();
    if (o instanceof MultiPartSigned) {
        MultiPartSigned mps = (MultiPartSigned) o;
        boolean validsig = mps.verifySignature();

        // could already get the other blocks
        // even if it wasn't a valid signature
    }
}
```

If the signature is invalid, the application can still access the data. There will also be other methods on

MultiPartSigned which allow setting of which keys or certificates to use when verifying the signature.

C.1.5 Creating a Message

There are two methods for creating an Encrypted/Signed message. Users will probably see an editor bean for the content types multipart/signed and multipart/encrypted. These beans would handle the UI components of allow the user to select how they wanted to encrypt/sign the message. The beans could be integrated into an application's Message Composition window.

C.1.5.1 Encrypted/Signed

The non-GUI method of creating the messages involves using the MultiPartEncrypted/Signed classes. The classes can be created and used as the content for a message. The following code shows how might work:

```
MultiPartEncrypted mpe = new MultiPartEncrypted();
// can setup parameters for how you want to encrypt the
// message otherwise it will use the user's preferences
// set the content you wish to encrypt (to encrypt multiple
// contents a multipart/mixed block should be used)
String ourContent = "Please encrypt me!";
mpe.setContent(ourContent);

MimeMessage m = new MimeMessage(session);
m.setContent(mpe);
```

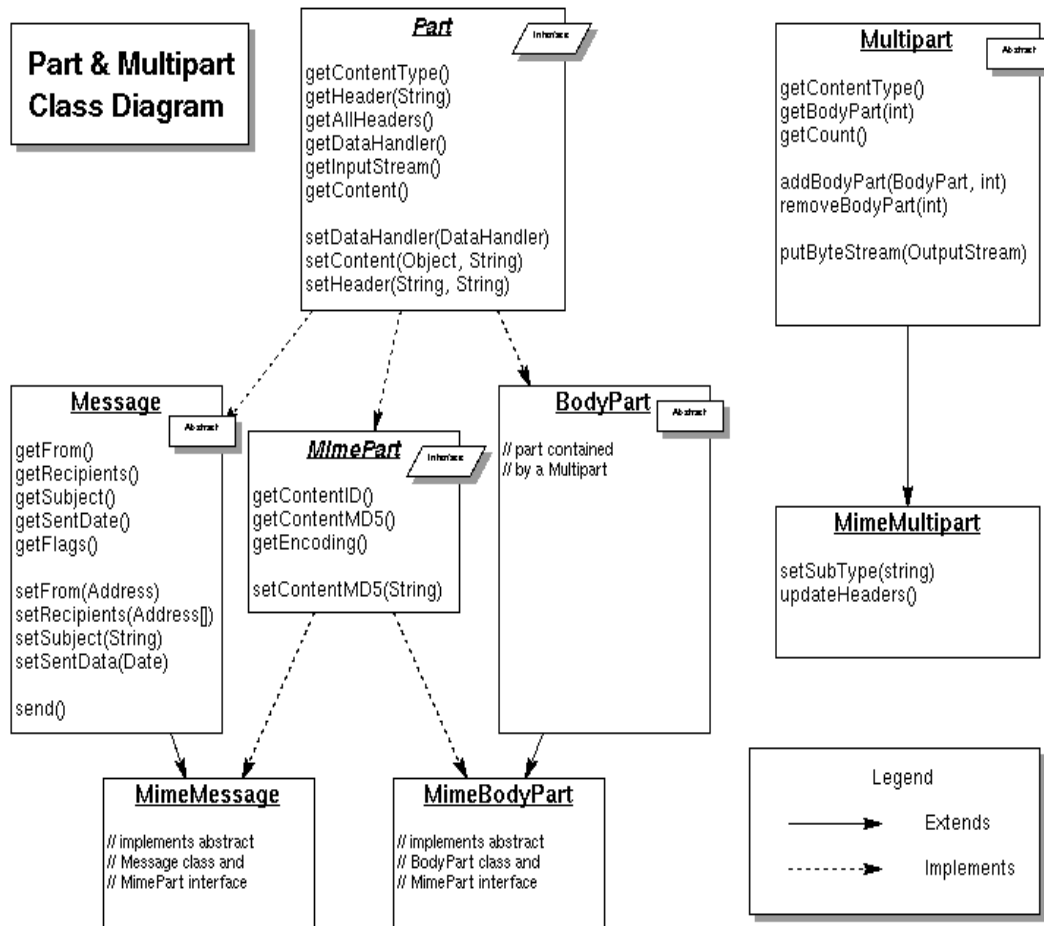

The message will be encrypted when the message is sent. There will be other methods which would allow the setting which encryption scheme is used and the keys involved.

The version is very similar to the Encrypted Message version, except that a MultiPartSigned object is created instead.

D

Part and Multipart Class Diagram

This Appendix illustrates relationships between Part interfaces and Message classes.

E

MimeMessage Object Hierarchy

This Appendix illustrates the MimeMessage object hierarchy.
